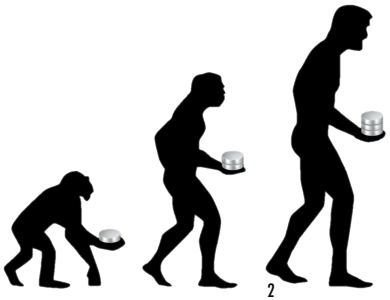
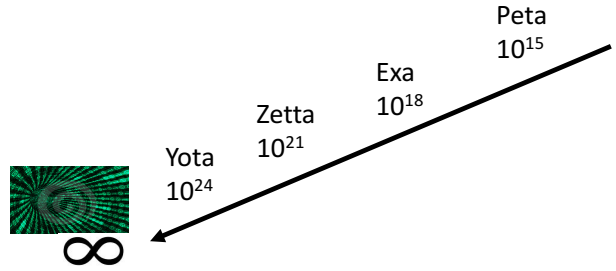
*"Design the **next generation** of **data processing systems & architectures** **guided by scientific requirements**"*

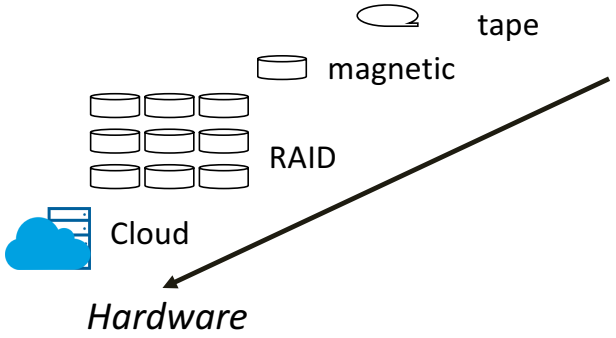


CLOUD DATA MANAGEMENT: SERVICES VIEWS

- Definition
- Querying and exploiting
- Manipulation

- Storage (persistency)
- Efficient retrieval (indexing, caching)
- Fault tolerance (recovery, replication)
- Maintenance





DBMS EVOLUTION

No more monolithic DBMS

Extensible, lightweight DBMS

Unbundled technology*

Component-based architectures* (thick-grain vs. fine-grain)

OO Frameworks

Components are providing Services

Blur the boundaries between OS & DBMS

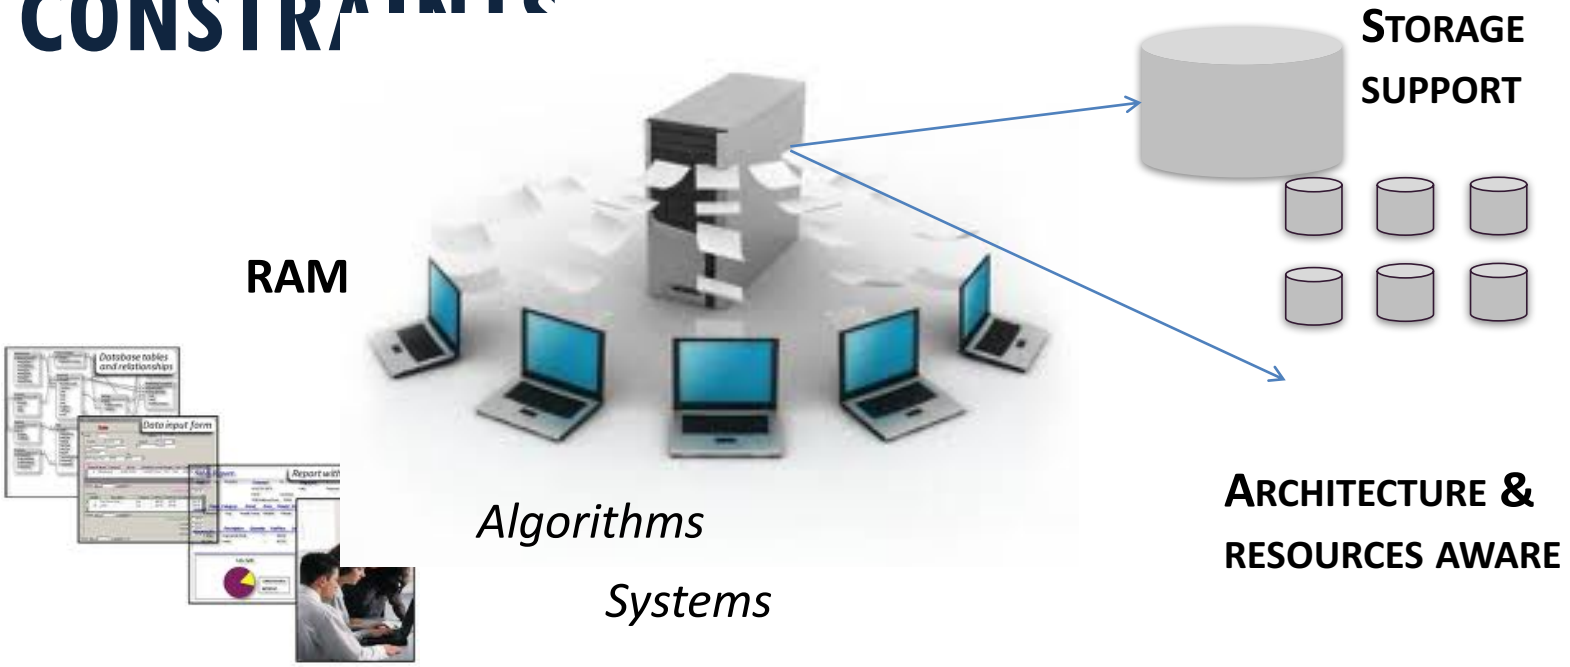
Self-adaptive Systems

Multi-tier architectures, Web, P2P, GRID, CLOUD,…

* See Dittrich, Geppert, Eds, “Component Database Systems”, MK 2000

* Chaudhuri & Weikum, Rethinking Database System Architecture: Towards a Self-tuning RISC-style Database System, VLDB 2000

DATA MANAGEMENT **WITH RESOURCES CONSTRAINTS**

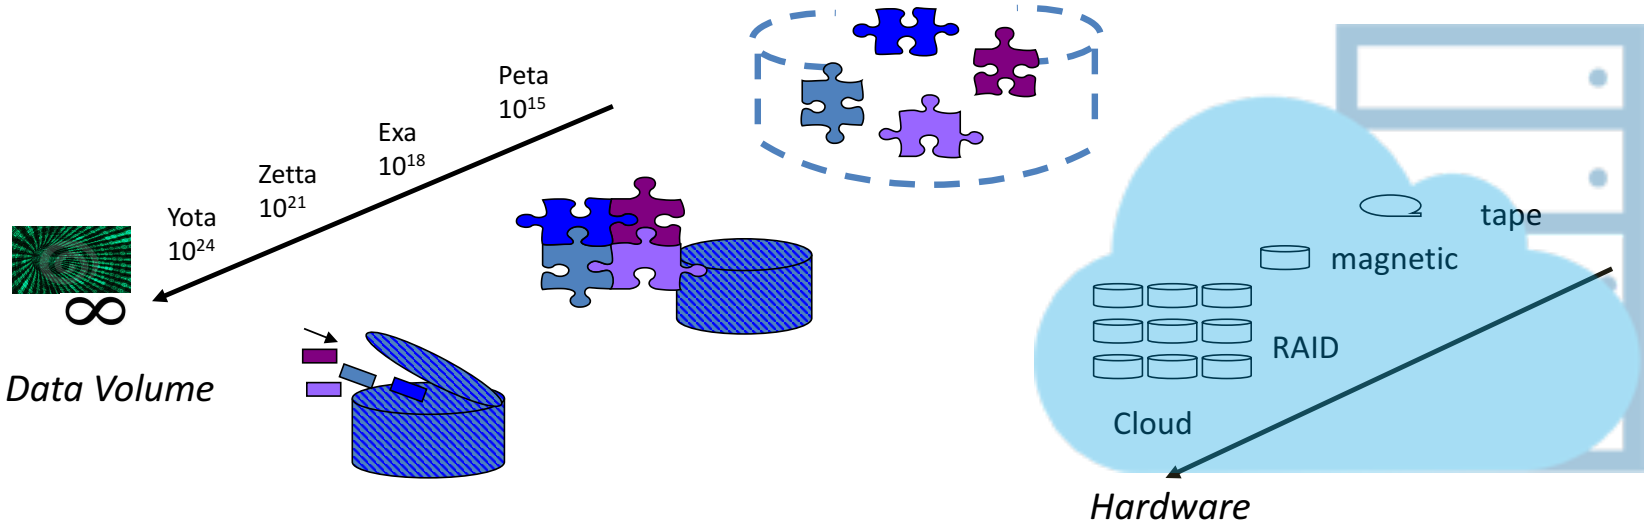


Efficiently manage and exploit data sets according to given specific storage, memory and computation resources

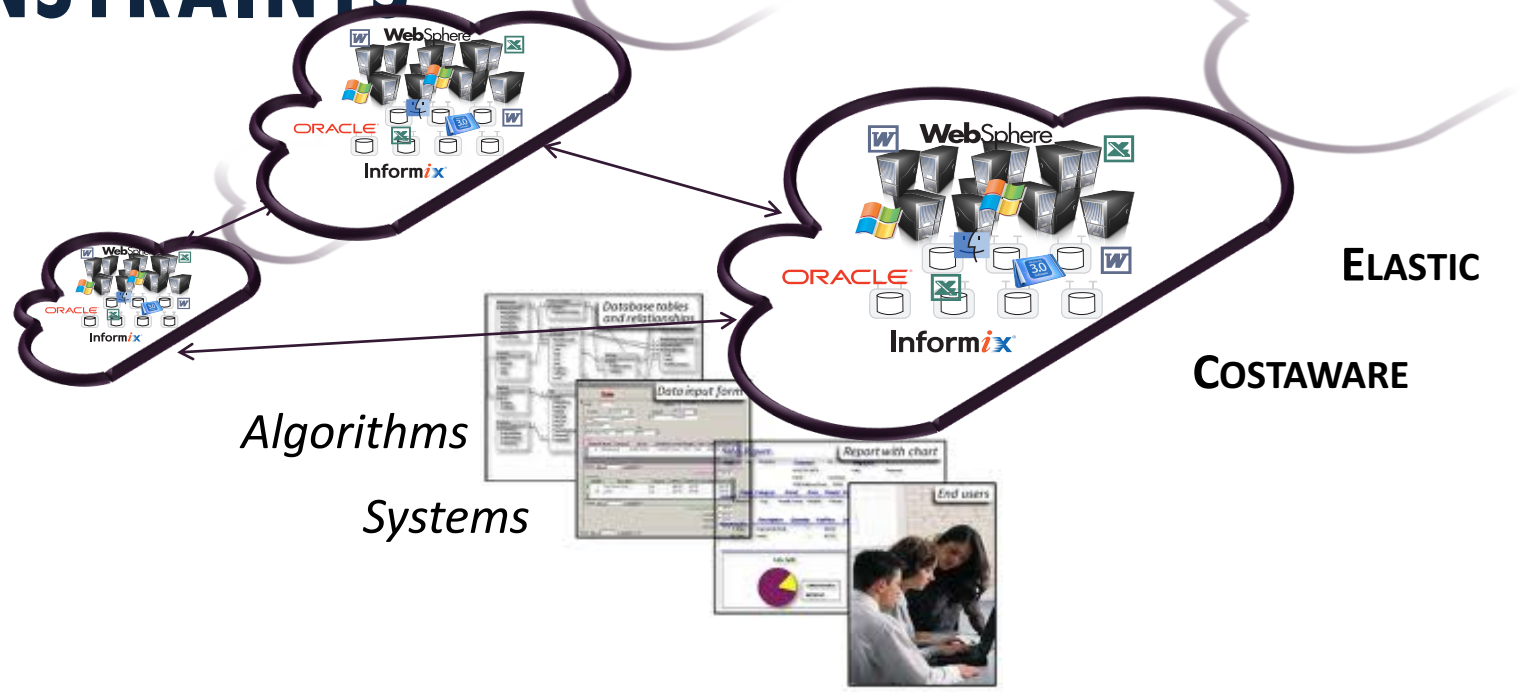
CLOUD DATA MANAGEMENT: SERVICES VIEWS

- Definition
- Querying and exploiting
- Manipulation

- Storage (persistency)
- Efficient retrieval (indexing, caching)
- Fault tolerance (recovery, replication)
- Maintenance



DATA MANAGEMENT **WITHOUT RESOURCES CONSTRAINTS**



Reduce the cost to manage and exploit data sets according to unlimited storage, memory and computation resources

CLOUD DATA MANAGEMENT WISH LIST

Scalability and elasticity are the keys in cloud data management

- Quality: efficiency, economic cost, provenance, user preferences and constraints
- Multi-tenancy: managing large number of small tenants
- Consistency and replication

Fault Tolerance

- If a query must restart each time a node fails, then long, complex queries are difficult to complete

Run in heterogeneous environments

- Should prevent the slowest node from making a disproportionate affect on total query performance

Operate on encrypted data

Interface with **data analytics** and **exploitation services**

CLOUD DATA MANAGEMENT: ASPECTS TO CONSIDER

Security [Agrawal2]

- Confidentiality
- Privacy

Data Analytics

- Large scale processing of complex queries
- Machine learning and data mining at large scale

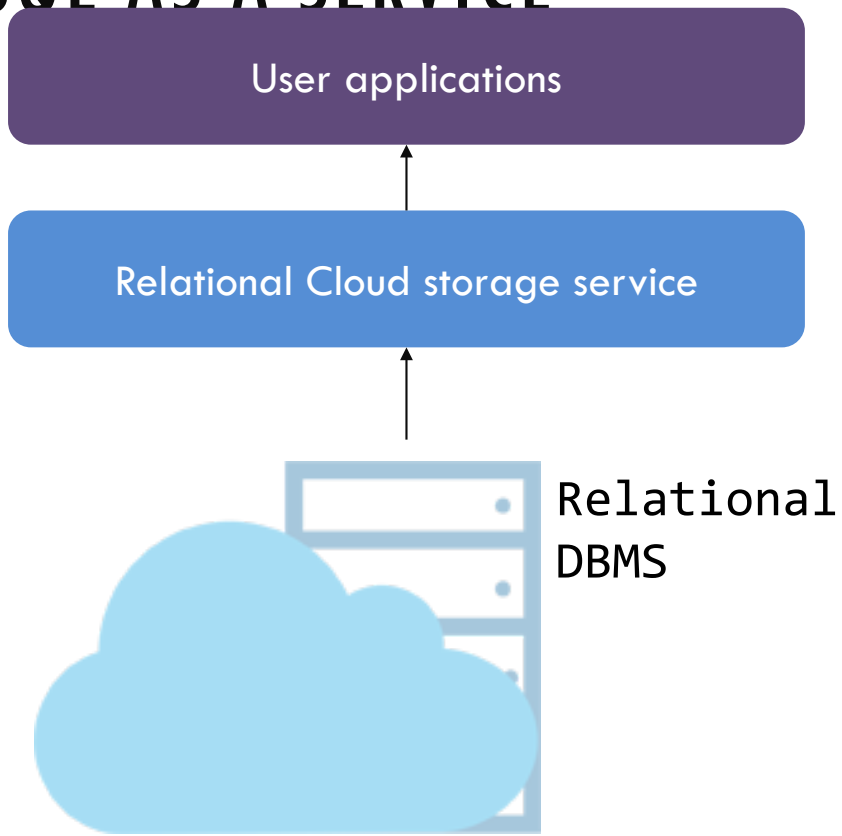
Multi-tenancy

- For OLTP [Agrawal1]
- For OLAP [Wong 2013]

Consistency, scalability and elasticity [Agrawal1]

- Replication and consistency models
- Elasticity

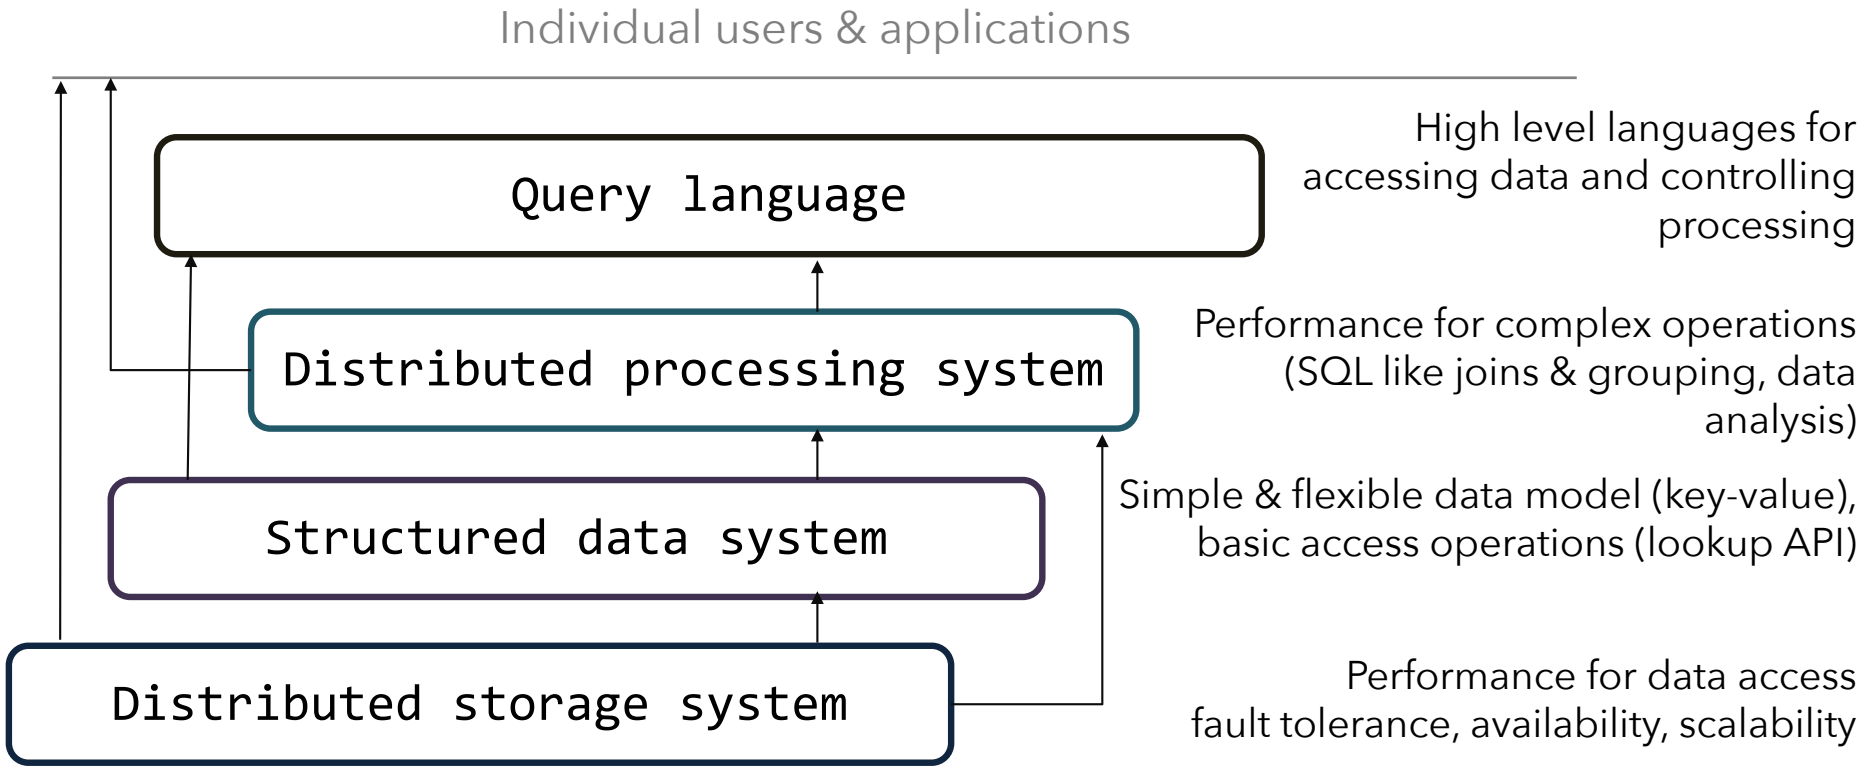
SQL AS A SERVICE



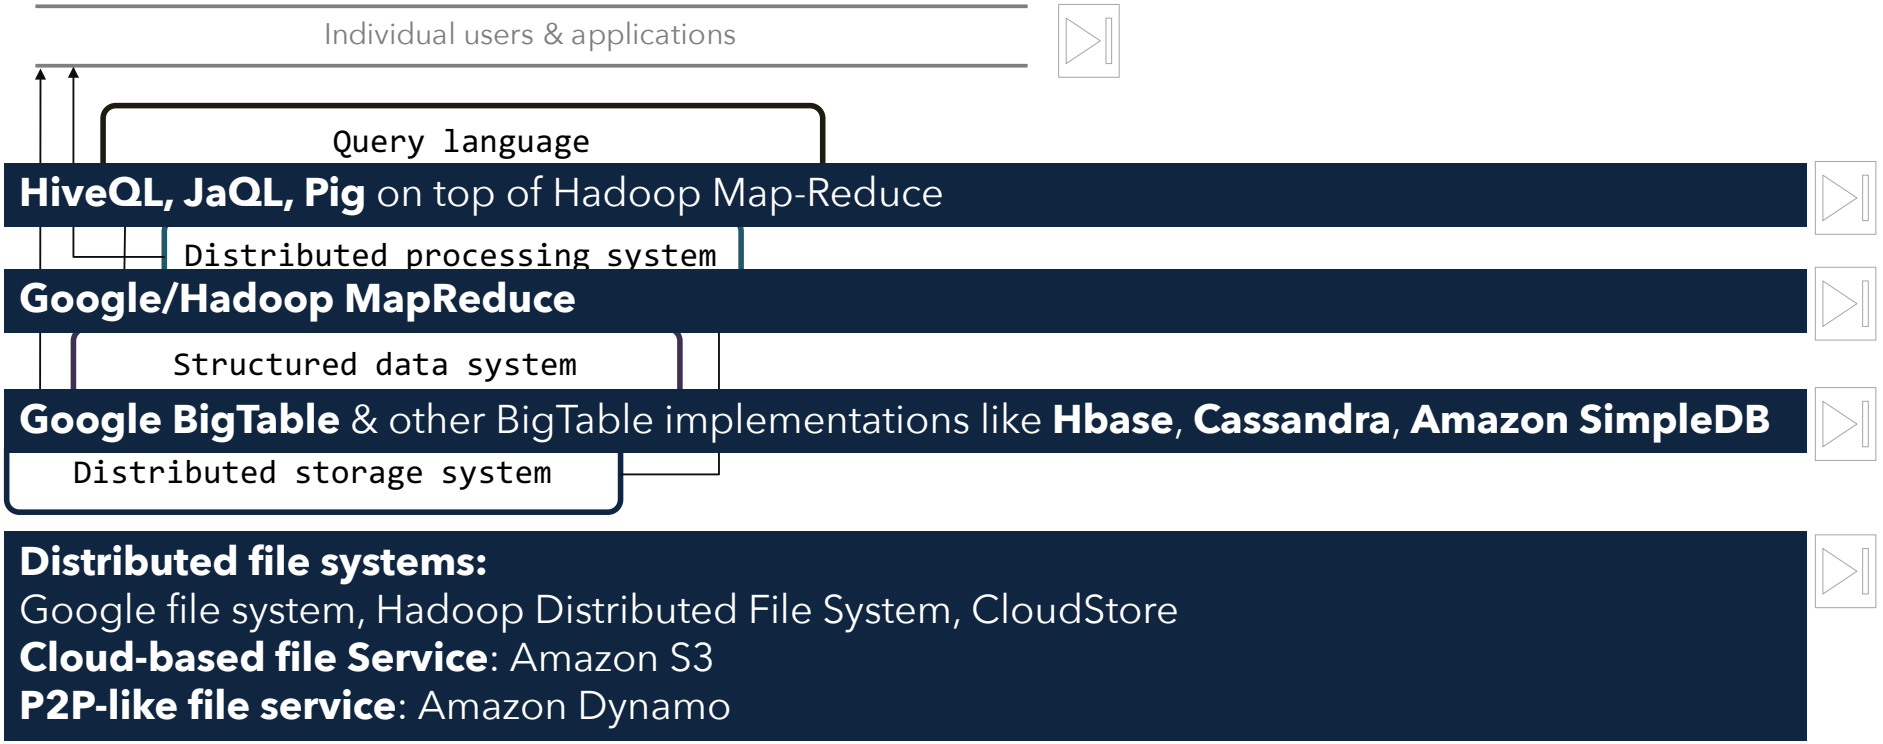
Relational model and SQL as a Service e.g. Amazon relational database service (RDS), MS SQL Azure

Implemented on top of parallel clusters of common DBMS servers e.g., MySQL MS SQL Server

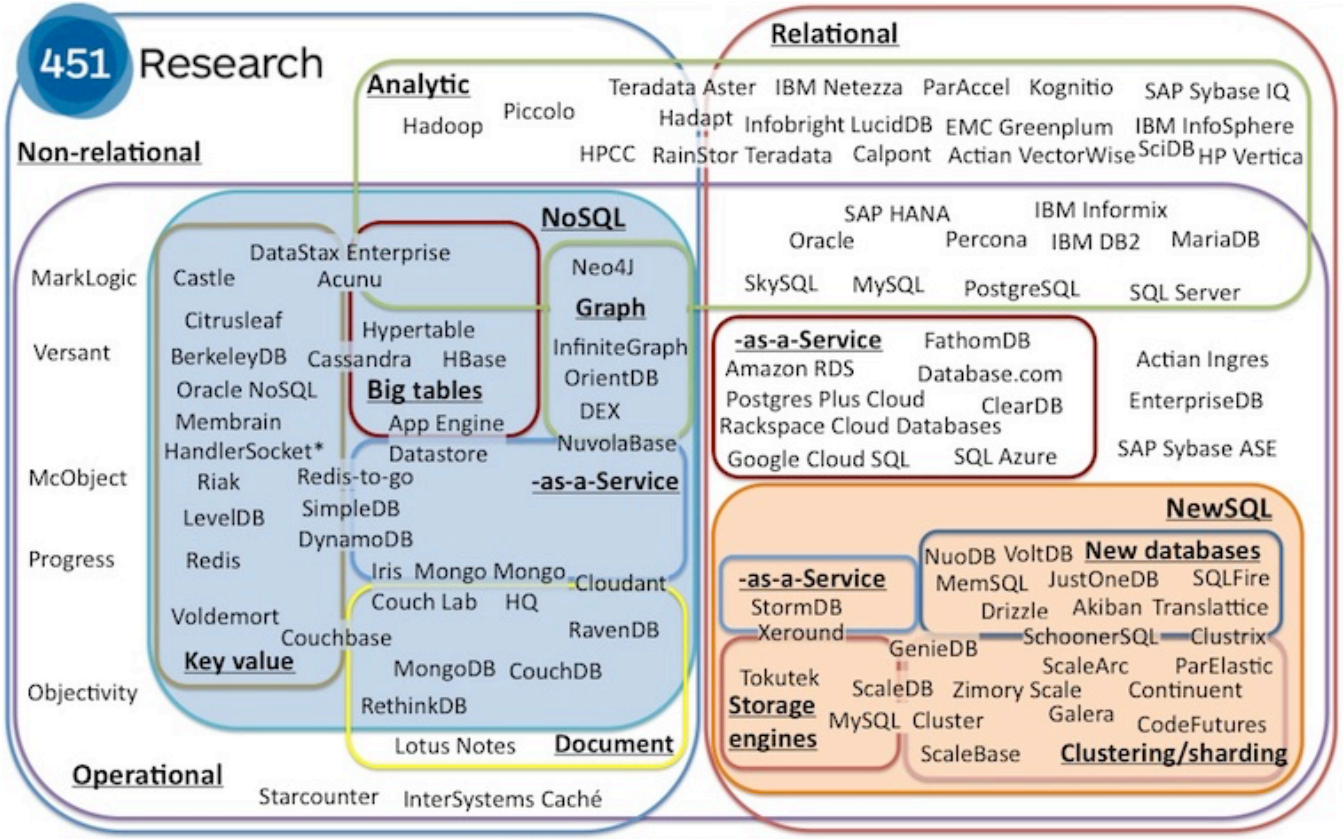
CLOUD DATA MANAGEMENT: FUNCTIONS VIEW



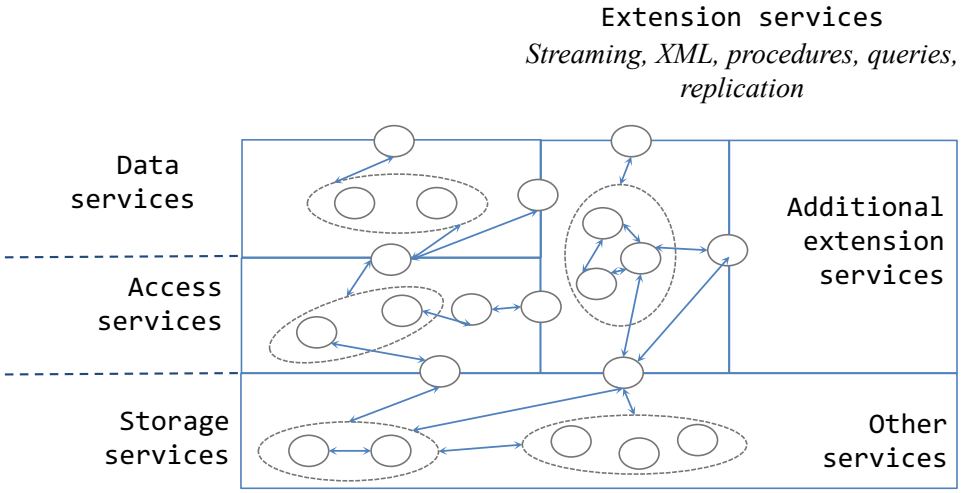
CLOUD DATA MANAGEMENT: FUNCTIONS VIEW

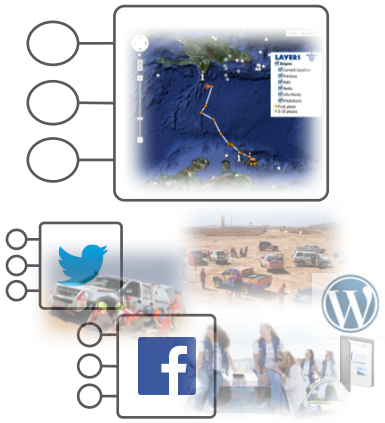


DATABASE LANDSCAPE



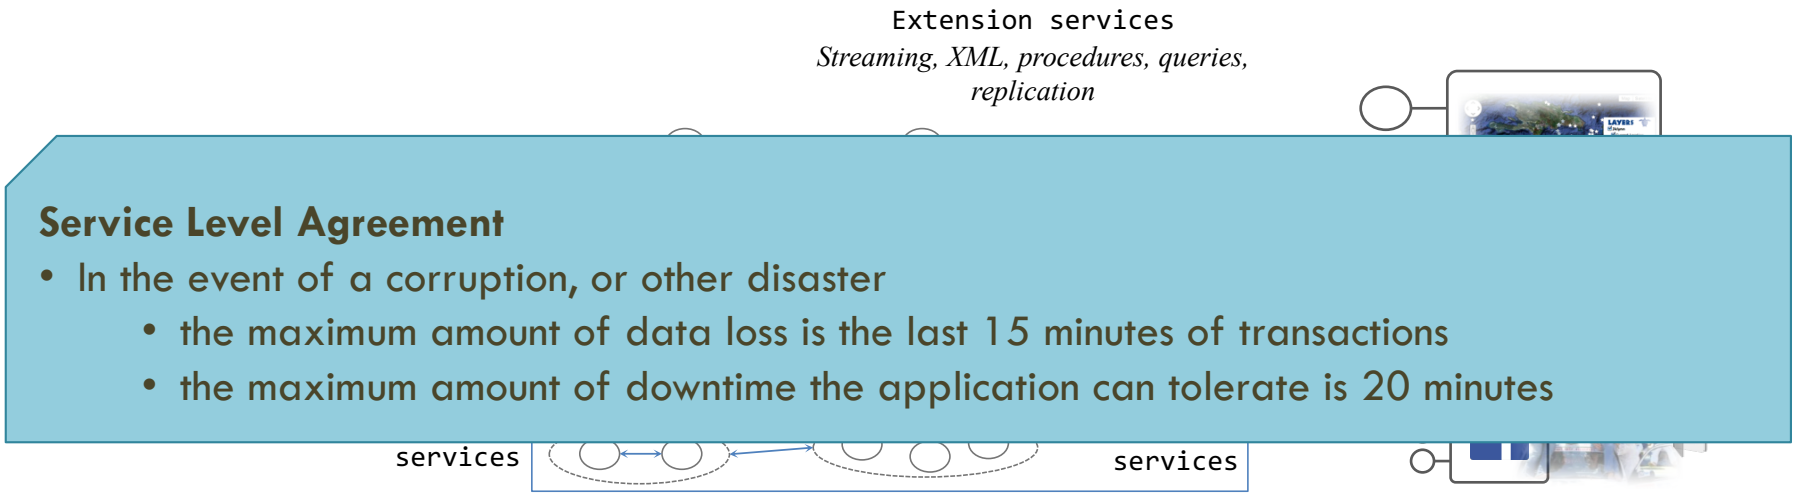
SERVICE ORIENTED DBMS





[1] Ionut Subasu, Patrick Ziegler, and Klaus R Dittrich. *Towards service-based data management systems*. In Workshop Proceedings of Datenbanksysteme in Business, Technologie und Web (BTW 2007)
Klaus R Dittrich and Andreas Geppert. *Component database systems*. Morgan Kaufmann, 2000.

SERVICE ORIENTED DBMS

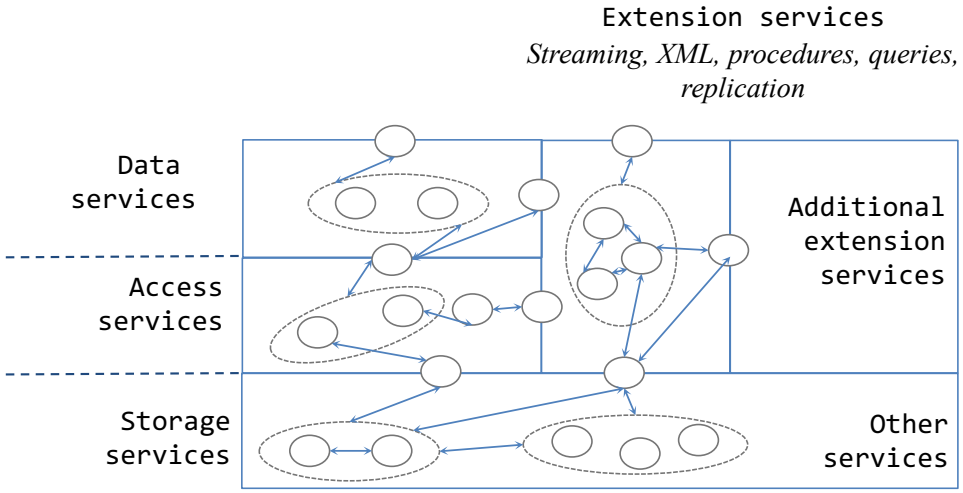


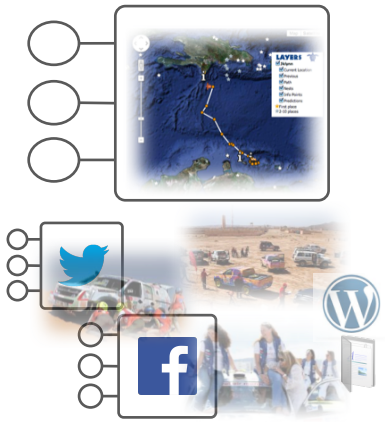
Service level agreement: the contracted delivery time of the service or performance

Required SLA: agreements between the user and SDBMS expressed as a combination of weighted measures associated to a query

[1] Ionut Subasu, Patrick Ziegler, and Klaus R Dittrich. *Towards service-based data management systems*. In Workshop Proceedings of Datenbanksysteme in Business, Technologie und Web (BTW 2007)
Klaus R Dittrich and Andreas Geppert. *Component database systems*. Morgan Kaufmann, 2000.

SERVICE ORIENTED DBMS





Service level agreement: the contracted delivery time of the service or performance

Required SLA: agreements between the user and SDBMS expressed as a combination of weighted measures associated to a query

[1] Ionut Subasu, Patrick Ziegler, and Klaus R Dittrich. *Towards service-based data management systems*. In Workshop Proceedings of Datenbanksysteme in Business, Technologie und Web (BTW 2007) Klaus R Dittrich and Andreas Geppert. *Component database systems*. Morgan Kaufmann, 2000.

CHALLENGES AND OBJECTIVE

How to combine, deploy, and deliver DBMS functionalities:

- **Compliant** to application/user requirements
- **Optimizing** the consumption of computing resources in the presence of **greedy** data processing tasks
- Delivered according to **Service Level Agreement (SLA)** contracts
- Deployed in **elastic** and distributed **platforms**

* See Dittrich, Geppert, Eds, “Component Database Systems”, MK 2000

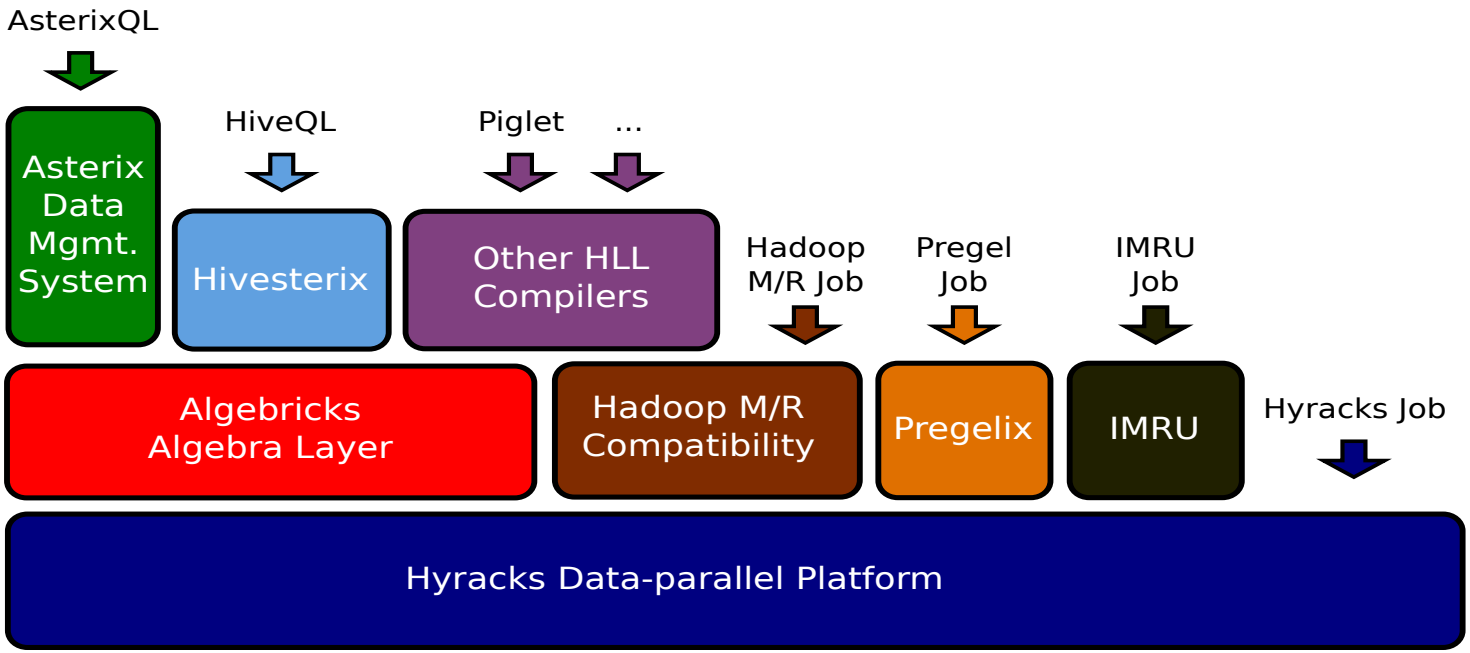
ASTERIX SOFTWARE STACK



GOOGLE BIG QUERY

Key Differences	BigQuery	MapReduce
What is it?	Query service for large datasets	Programming model for processing large datasets
Common use cases	Ad hoc and trial-and- error interactive query of large dataset for quick analysis and troubleshooting	Batch processing of large dataset for time-consuming data conversion or aggregation
Sample use cases		
OLAP/BI use case	Yes	No
Data Mining use case	Partially (e.g. preflight data analysis for data mining)	Yes
Very fast response	Yes	No (takes minutes - days)
Easy to use for non-programmers (analysts, tech support, etc)	Yes	No (requires Hive/Tenzing)
Programming complex data processing logic	No	Yes
Processing unstructured data	Partially (regular expression matching on text)	Yes

Google BigQuery Pricing

BigQuery uses a columnar data structure, which means that for a given query, you are only charged for data processed in each column, not the entire table. The first 100GB of data processed per month is at no charge

Pricing Table

Resource	Pricing	Default Limits
Storage	$0.12 (per GB/month)	2TB
Interactive Queries	$0.035 (per GB Processed) **	20,000 Queries Per Day (QPD) 20TB of Data Processed Per Day
Batch Queries	$0.02 (per GB processed)	20,000 Total Queries Per Day (QPD)

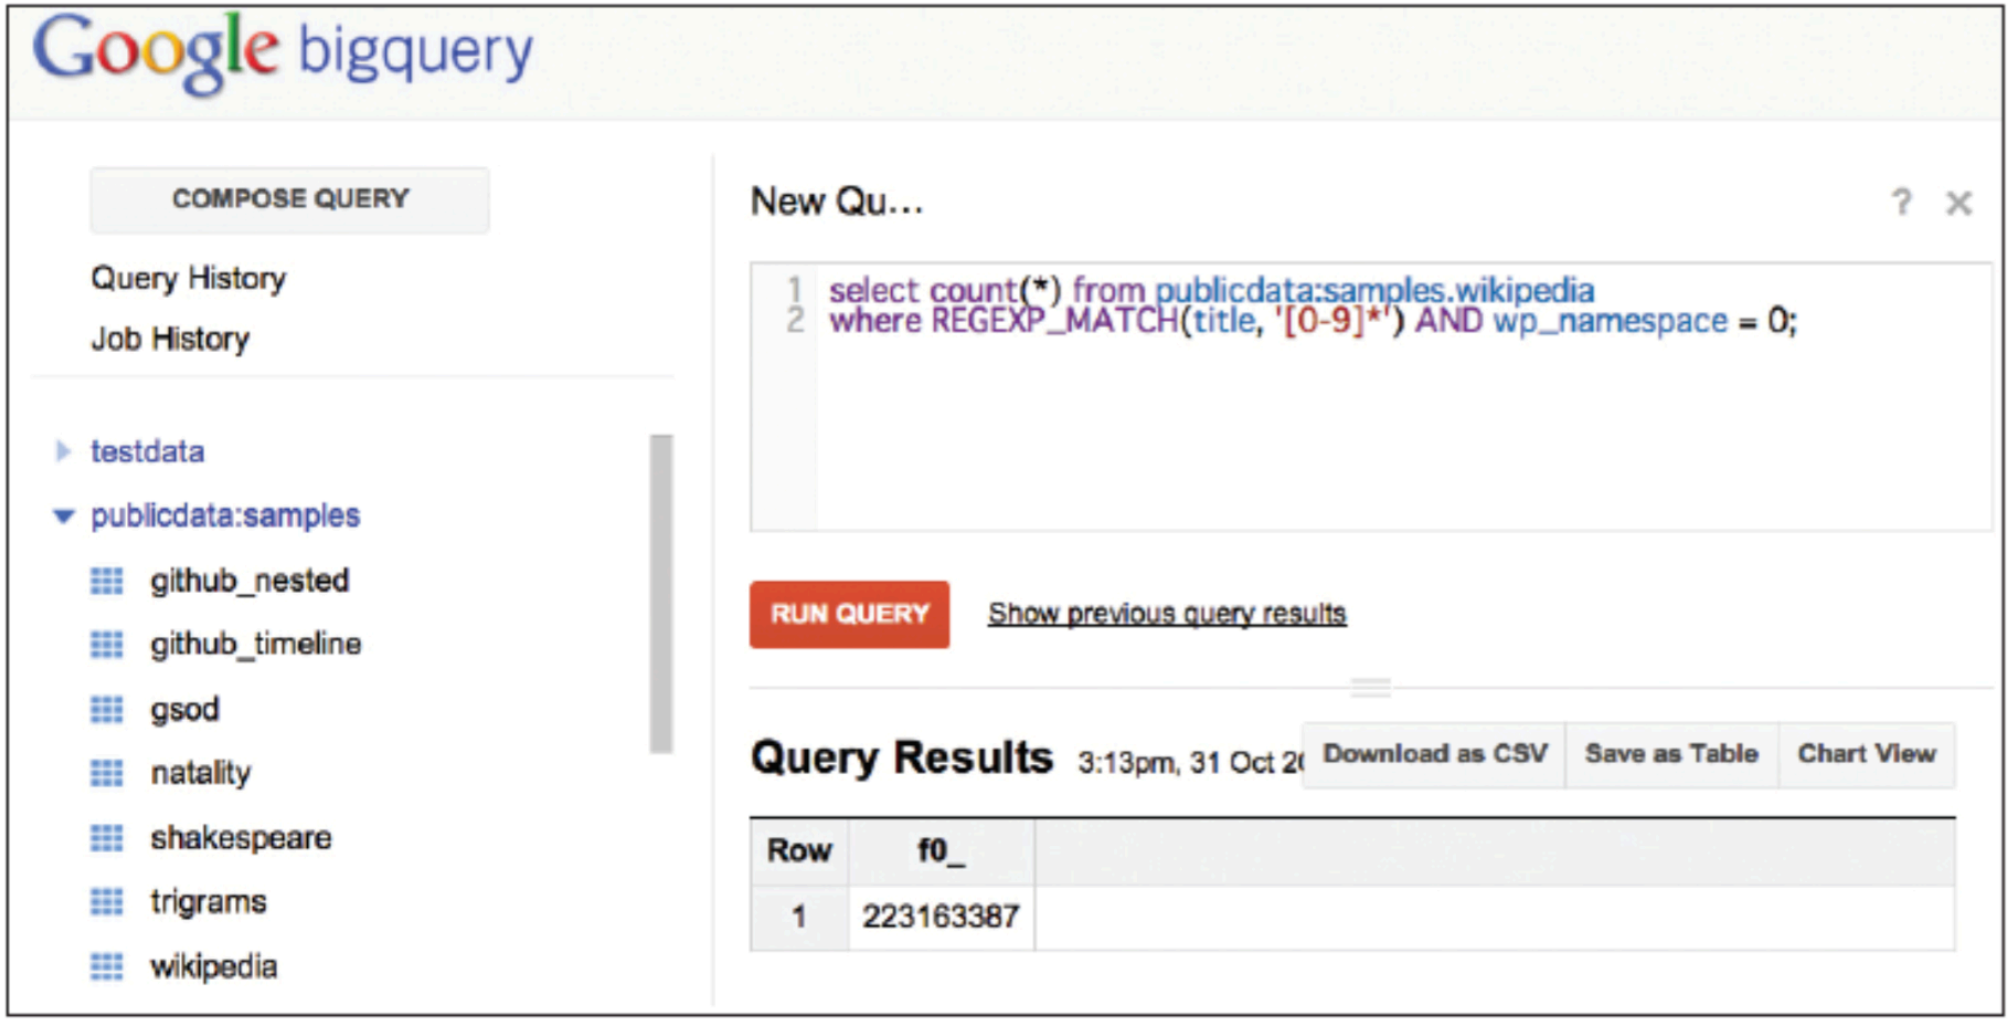


Figure 1 Querying Sample Wikipedia Table on BigQuery

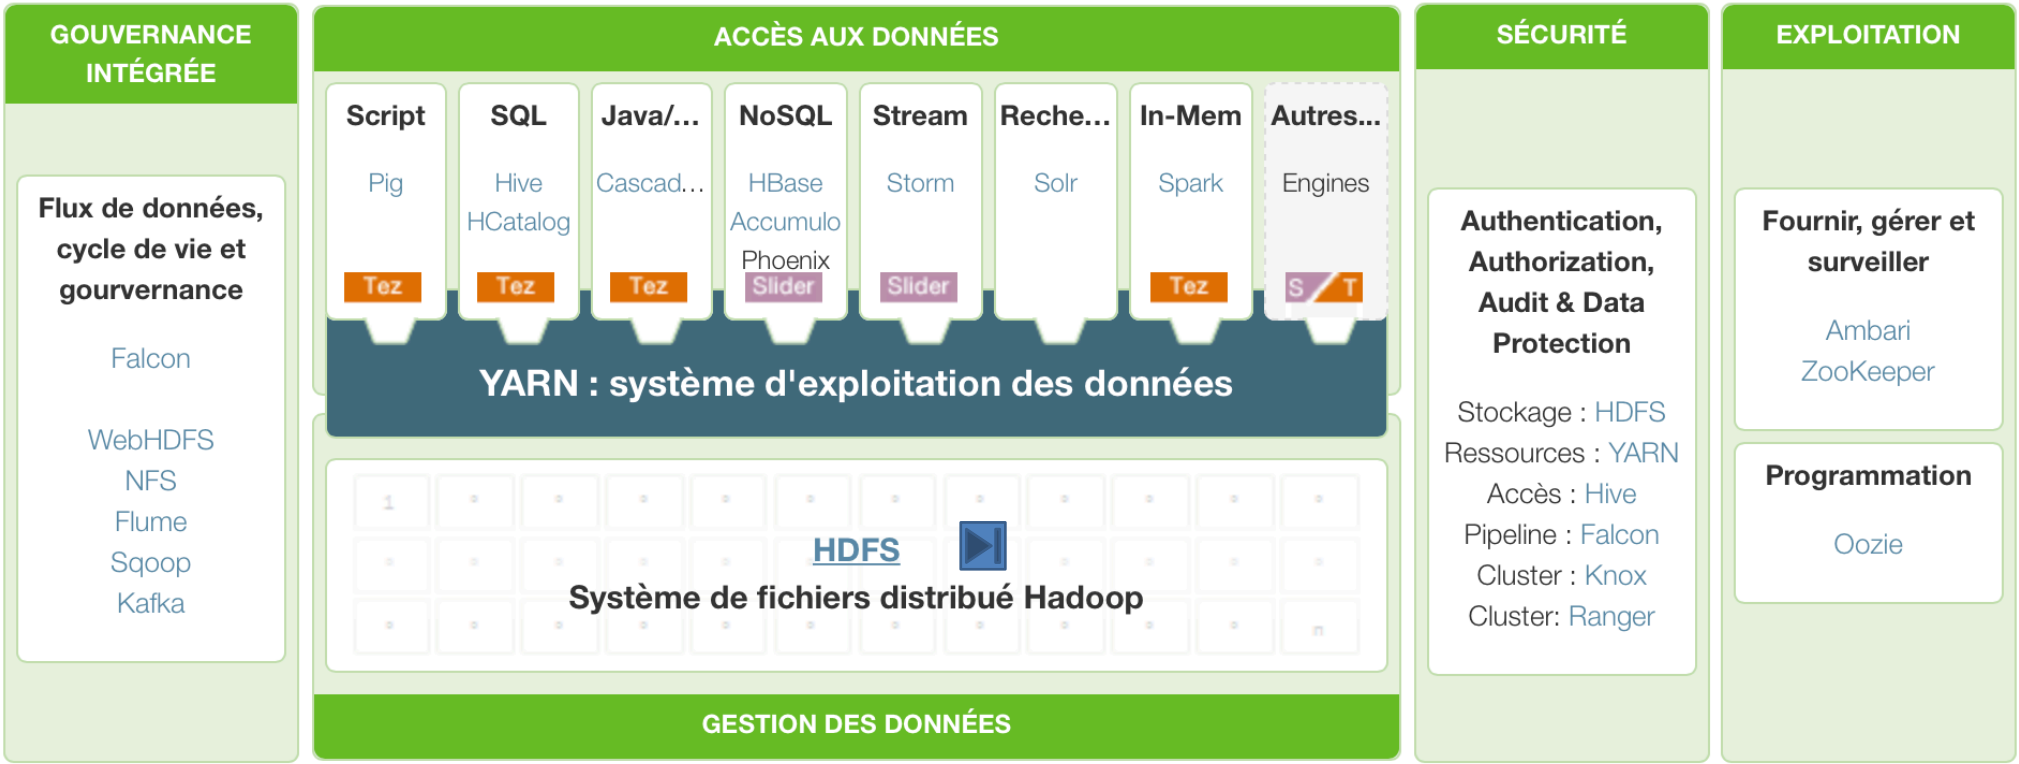
HORTONWORKS



http://fr.hortonworks.com

PRINCIPLE

$$\text{map: } (k_1, v_1) \longrightarrow [(k_2, v_2)]$$
$$\text{reduce: } (k_2, [v_2]) \longrightarrow [(k_3, v_3)]$$

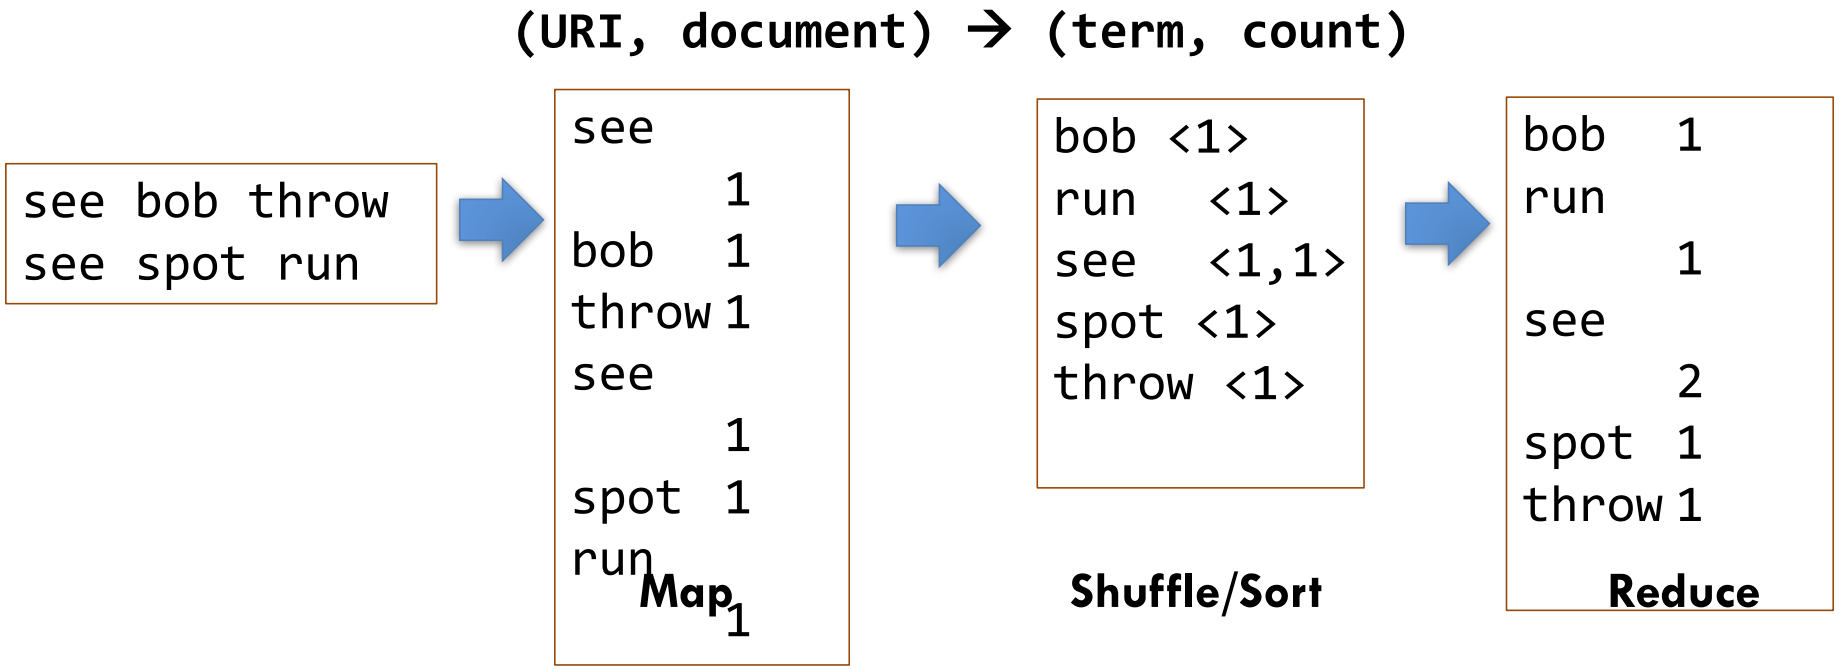
Stage 1: Apply a user-specified computation over all input records in a dataset.

- These operations occur in parallel and yield intermediate output (**key-value** pairs)

Stage 2: Aggregate intermediate output by another user-specified computation

- Recursively applies a function on every pair of the list

COUNTING WORDS



KEY VALUE PAIRS

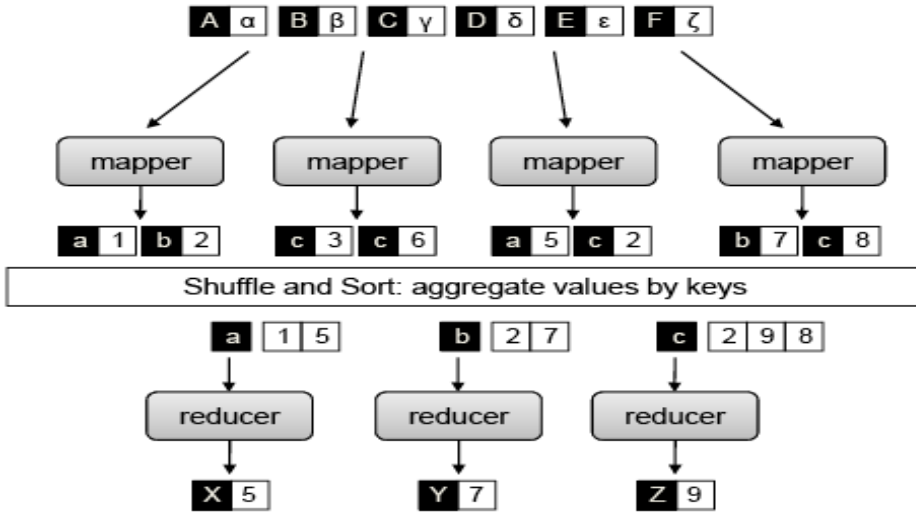
Basic data structure in MapReduce, keys and values may be

- primitive such as integers, floating point values, strings, and raw bytes
- arbitrarily complex structures (lists, tuples, associative arrays, etc.)

Part of the design of MapReduce algorithms involves imposing the key-value structure on arbitrary datasets

- For a collection of web pages, keys may be URLs and values may be the actual HTML content.
- For a graph, keys may represent node ids and values may contain the adjacency lists of those nodes

MAP REDUCE EXAMPLE



```
1: class Mapper
2:     method Map(docid a, doc d)
3:         for all term t ∈ doc d do
4:             Emit(term t, count 1)

1: class Reducer
2:     method Reduce(term t, counts [c1, c2, ...])
3:         sum ← 0
4:         for all count c ∈ counts [c1, c2, ...] do
5:             sum ← sum + c
6:         Emit(term t, count sum)
```

MAP REDUCE PHASES

Initialisation

Map: *record reader, mapper, combiner, and partitioner*

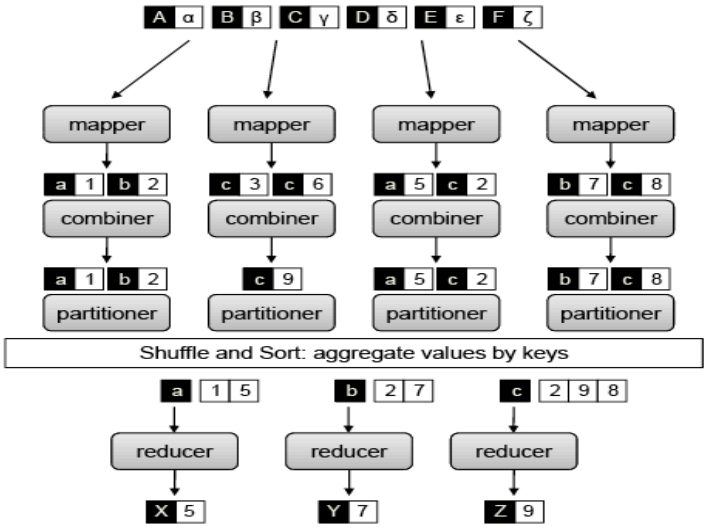
Reduce: *shuffle, sort, reducer, and output format*

Partition input (key, value) pairs into chunks run map() tasks in parallel

After all map()'s have been completed consolidate the values for each unique emitted key

Partition space of output map keys, and run reduce() in parallel

MAP REDUCE ADDITIONAL ELEMENTS



Partitioners are responsible for dividing up the intermediate key space and assigning intermediate key-value pairs to reducers

- the partitioner species the task to which an intermediate key-value pair must be copied

Combiners are an optimization in MapReduce that allow for local aggregation before the shuffle and sort phase

COUNTING WORDS: BASIC ALGORITHM

```
1: class Mapper
2:     method Map(docid a, doc d)
3:         for all term t ∈ doc d do
4:             Emit(term t, count 1)

1: class Reducer
2:     method Reduce(term t, counts [c1, c2, ...])
3:         sum ← 0
4:         for all count c ∈ counts [c1, c2, ...] do
5:             sum ← sum + c
6:         Emit(term t, count sum)
```

the mapper emits an intermediate key-value pair for each term observed, with the term itself as the key and a value of one

reducers sum up the partial counts to arrive at the final count

LOCAL AGGREGATION

Combiner technique

- Aggregate term counts across the documents processed by each map task
- Provide a general mechanism within the MapReduce framework to reduce the amount of intermediate data generated by the mappers
- Reduction in the number of intermediate key-value pairs that need to be shuffled across the network
  - from the order of total number of terms in the collection to the order of the number of ***unique*** terms in the collection

```
1: class Mapper
2:     method Map(docid a, doc d)
3:         H ← new AssociativeArray
4:         for all term t ∈ doc d do
5:             H{t} ← H{t} + 1
6:         for all term t ∈ H do
7:             Emit(term t, count H{t})
```

IN-MAPPER COMBINING PATTERN: ONE STEP FURTHER

The workings of this algorithm critically depends on the details of how map and reduce tasks in Hadoop are executed

Prior to processing any input key-value pairs, the mapper's `Initialize` method is called

- which is an API hook for user-specified code
- We initialize an associative array for holding term counts
- Since it is possible to preserve state across multiple calls of the Map method (for each input key-value pair), we can
  - continue to accumulate partial term counts in the associative array across multiple documents,
  - emit key-value pairs only when the mapper has processed all documents

Transmission of intermediate data is deferred until the `Close` method in the pseudo-code

```
1: class Mapper
2:     method Initialize
3:         H ← new AssociativeArray
4:     method Map(docid a, doc d)
5:         for all term t ∈ doc d do
6:             H{t} ← H{t} + 1
7:     method Close
8:         for all term t ∈ H do
9:             Emit(term t, count H{t})
```

IN-MAPPER COMBINING PATTERN: ADVANTAGES

Provides control over when local aggregation occurs and how it exactly takes place

- Hadoop makes no guarantees on how many times the combiner is applied, or that it is even applied at all
- The execution framework has the option of using it, perhaps multiple times, or not at all
- Such indeterminism is unacceptable, which is exactly why programmers often choose to perform their own local aggregation in the mappers

In-mapper combining will typically be more efficient than using actual combiners.

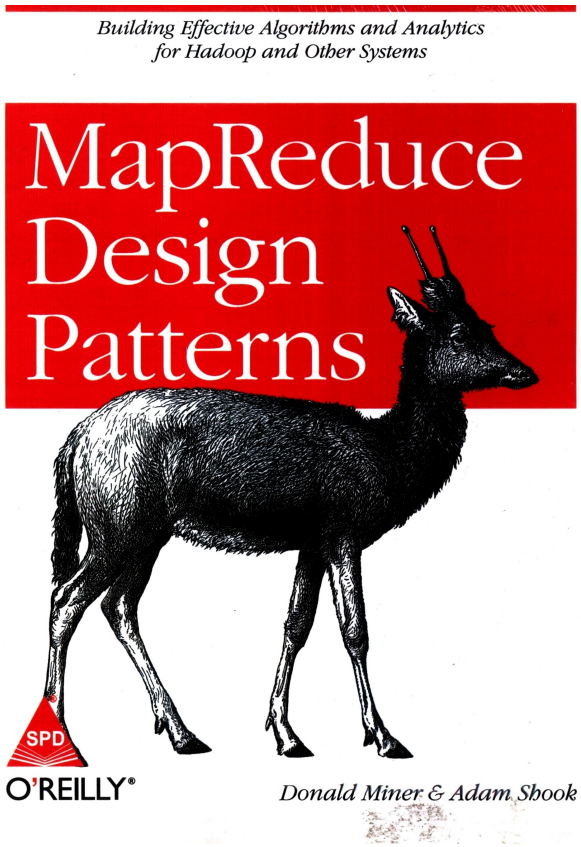
- One reason for this is the additional overhead associated with actually materializing the key-value pairs
  - Combiners reduce the amount of intermediate data that is shuffled across the network, but don't actually reduce the number of key-value pairs that are emitted by the mappers in the first place
  - The mappers will generate only those key-value pairs that need to be shuffled across the network to the reducers
  - Avoid unnecessary object creation and destruction (garbage collection takes time), and, object serialization and deserialization (when intermediate key-value pairs fill the in-memory buffer holding map outputs and need to be temporarily spilled to disk)

IN-MAPPER COMBINING PATTERN: LIMITATIONS

Breaks the functional programming underpinnings of MapReduce, since state is being preserved across multiple input key-value pairs

There is a fundamental scalability bottleneck associated with the in-mapper combining pattern

- It critically depends on having sufficient memory to store intermediate results until the mapper has completely processed all key-value pairs in an input split
- One common solution to limiting memory usage is to "block" input key-value pairs and "flush" in-memory data structures periodically
- Instead of emitting intermediate data only after every key-value pair has been processed, emit partial results after processing every n key-value pairs
  - Implemented with a counter variable that keeps track of the number of input key-value pairs that have been processed
  - The mapper could keep track of its own memory footprint and flush intermediate key-value pairs once memory usage has crossed a certain threshold
  - Memory size empirically determined: difficult due to concurrent access to memory



MAP REDUCE PATTERNS

MapReduce design patterns, O'Relly

MAP – REDUCE DESIGN PATTERNS

SUMMARIZATION

Numerical

- Minimum, maximum, count, average, median-standard deviation

Inverted index

- Wikipedia inverted index

Counting with counters

- Count number of records, a small number of unique instances, summations
- Number of users per state

FILTERING

Filtering

- Closer view of data, tracking event threads, distributed grep, data cleansing, simple random sampling, remove low scoring data

Bloom

- Remove most of nonwatched values, prefiltering data for a set membership check
- Hot list, Hbase query

Top ten

- Outlier analysis, select interesting data, catchy dashbords
- Top ten users by reputation

Distinct

- Deduplicate data, getting distinct values, protecting from inner join explosion
- Distinct user ids

DATA ORGANIZATION

Structured to hierarchical

- Prejoining data, preparing data for Hbase or MongoDB
- Post/comment building for StackOverflow, Question/Answer building

Partitioning

- Partitioning users by last access date

Binning

- Binning by Hadoop-related tags

Total order sorting

- Sort users by last visit

Shuffling

- Anonymizing StackOverflow comments

JOIN

Reduce side join

- Multiple large data sets joined by foreign key
- User – comment join

Reduce side join with bloom filter

- Reputable user – comment join

Replicated join

- Replicated user – comment join

Composite join

- Composite user – comment join

Cartesian product

- Comment comparison

NUMERICAL SUMMARIZATION PATTERN

The numerical summarizations pattern is a general pattern for calculating aggregate statistical values over a data collection

Intent

- Group records together by a key field and calculate a numerical aggregate per group to get a top-level view of the larger data set
- θbe a generic numerical summarization function we wish to execute over some list of values $(v_1, v_2, v_3, \ldots, v_n)$ to find a value λ, i.e. $\lambda = \theta(v_1, v_2, v_3, \ldots, v_n)$. Examples of θ include a minimum, maximum, average, median, and standard deviation

Motivation and applicability

- Group logins by the hour of the day and perform a count of the number of records in each group, group advertisements by types to determine how affective ads are for better targeting
- Dealing with numerical data or counting
- The data can be grouped by specific fields

STRUCTURE

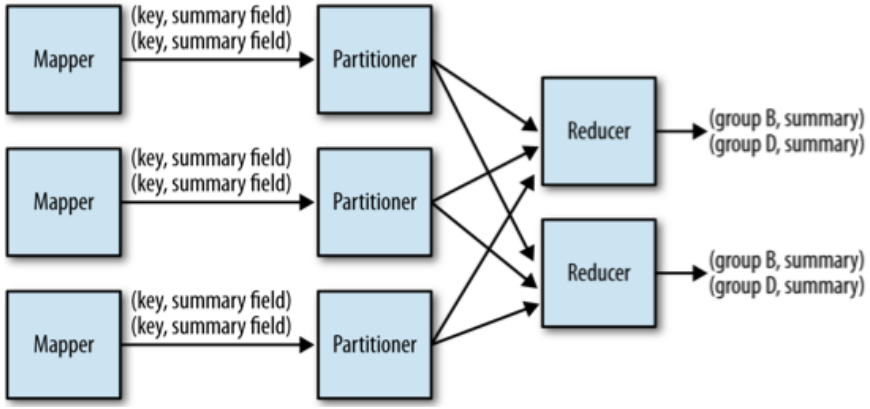
The mapper outputs keys that consist of each field to group by, and values consisting of any pertinent numerical items

The combiner can greatly reduce the number of intermediate key/value pairs to be sent across the network to the reducers for some numerical summarization functions

- If the function θ is an associative and commutative operation, it can be used for this purpose
- If you can arbitrarily change the order of the values and you can group the computation arbitrarily

The reducer

- receives a set of numerical values $(v_1, v_2, v_3, \ldots, v_n)$ associated with a group-by key records to perform the function $\lambda = \theta(v_1, v_2, v_3, \ldots, v_n)$
- The value of λ is output with the given input key



RESEMBLANCES AND PERFORMANCE ANALYSIS

Resemblances

SQL

The Numerical Aggregation pattern is analogous to using aggregates after a GROUP BY in SQL:

```
SELECT MIN(numericalcol1), MAX(numericalcol1),
       COUNT(*) FROM table GROUP BY groupcol2;
```

Pig

The GROUP ... BY expression, followed by a FOREACH ... GENERATE:

```
b = GROUP a BY groupcol2;
c = FOREACH b GENERATE group, MIN(a.numericalcol1),
       MAX(a.numericalcol1), COUNT_STAR(a);
```

Performance analysis

Aggregations performed by jobs using this pattern typically perform well when the combiner is properly used

These types of operations are what MapReduce was built for

Source: http://indoos.wordpress.com/2010/08/16/hadoop-ecosystem-world-map/

hands on

Conclusions & Perspectives

CONCLUSIONS

Data collections

- **New scales:** bronto scale due to emerging IoT
- **New types**: thick, long hot, cold
- New **quality measures**: QoS, QoE, SLA

Data **processing** & **analytics**

- Complex jobs, stream analytics are still open issues
- Economic cost model & business models (Big Data value & pay-as-U-go)

Multi-cloud: elasticity, quality, SLA

TODO LIST

QoS based event flow composition
Economy based data delivery
SLA guided data integration
Coordination based parallel data processing
Optimization of different types of queries

Pivot NoSQL data model
Distributed polyglot (big) database engineering
Extended YSCB NoSQL stores benchmark

NoSQL
Data science
Cloud *services*
Big *data*
Autonomous DaaS
Map reduce
No off the shelf DBMS

DISTRIBUTED FILE SYSTEM

Abandons the separation of computation and storage as distinct components in a cluster

- Google File System (GFS) supports Google's proprietary implementation of MapReduce;
- In the open-source world, HDFS (Hadoop Distributed File System) is an open-source implementation of GFS that supports Hadoop

The main idea is to divide user data into blocks and replicate those blocks across the local disks of nodes in the cluster

Adopts a master–slave architecture

- Master (`namenode` HDFS) maintains the file namespace (metadata, directory structure, file to block mapping, location of blocks, and access permissions)
- Slaves (`datanode` HDFS) manage the actual data blocks

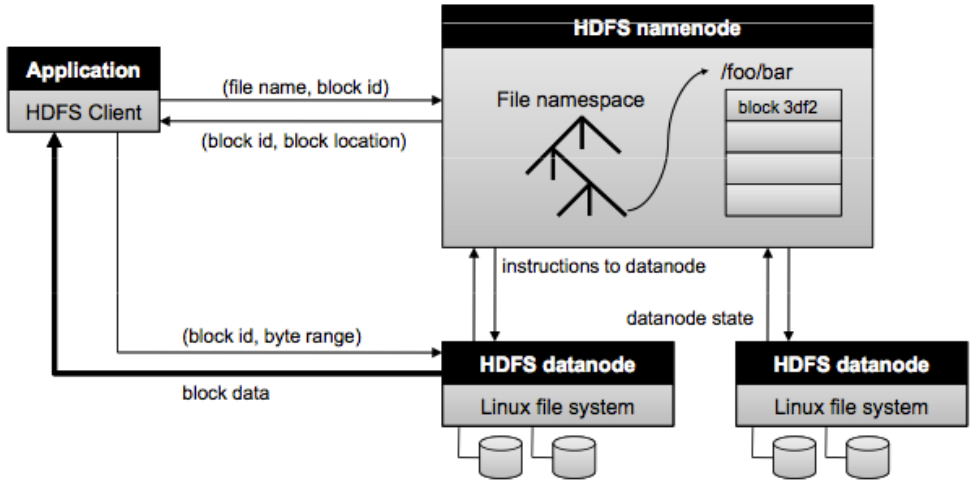
HFDS GENERAL ARCHITECTURE

An application client wishing to read a file (or a portion thereof) must first contact the `namenode` to determine where the actual data is stored

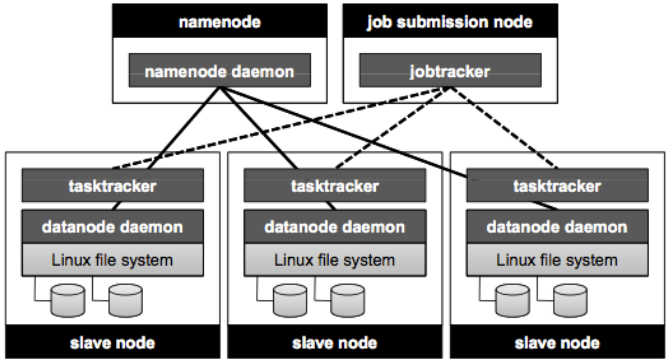
The `namenode` returns the relevant `block id` and the `location` where the block is held (i.e., which `datanode`)

The client then contacts the `datanode` t retrieve the data.

HDFS lies on top of the standard OS stack (e.g., Linux): blocks are stored on standard single-machine file systems



HADOOP CLUSTER ARCHITECTURE



The HDFS **namenode** runs the namenode daemon

The job submission node runs the **jobtracker**, which is the single point of contact for a client wishing to execute a MapReduce job

The **jobtracker**

- Monitors the progress of running MapReduce jobs
- Is responsible for coordinating the execution of the mappers and reducers
- Tries to take advantage of data locality in scheduling map tasks

HADOOP CLUSTER ARCHITECTURE

Tasktracker

- It accepts tasks (Map, Reduce, Shuffle, etc.) from JobTracker
- Each TaskTracker has a number of slots for the tasks: these are execution slots available on the machine or machines on the same rack
- It spawns a separate JVM for execution of the tasks
- It indicates the number of available slots through the hearbeat message to the JobTracker

HDFS PROPERTIES

HDFS stores **three separate** copies of each data block to ensure both reliability, availability, and performance

In large clusters, the three replicas are spread across different physical racks,

- HDFS is resilient towards two common failure scenarios individual `datanode` crashes and failures in networking equipment that bring an entire rack offline.
- Replicating blocks across physical machines also increases opportunities to **co-locate data** and processing in the scheduling of MapReduce jobs, since multiple copies yield more opportunities to exploit locality

To create a new file and write data to HDFS

- The application client contacts the `namenode`
- The `namenode`
  - updates the file namespace after checking permissions and making sure the file doesn't already exist
  - allocates a new block on a suitable datanode
- The application is directed to stream data directly to it
- From the initial `datanode`, data is further propagated to additional replicas

NOSQL STORES CHARACTERISTICS

Simple operations

- Key lookups reads and writes of one record or a small number of records
- No complex queries or joins
- Ability to dynamically add new attributes to data records

High performance

- Efficient use of distributed indexes and RAM for data storage
- Weak consistency model
- Limited transactions

- **Horizontal scalability**
  - Distribute data and operations over many servers
  - Replicate and distribute data over many servers
  - No shared memory or disk

Next generation databases mostly addressing some of the points: being **non-relational, distributed, open-source** and **horizontally scalable** [http://nosql-database.org]

so now we have NoSQL databases

- Data model
- Consistency
- Storage
- Durability

- Availability
- Query support

Data stores designed to scale simple OLTP-style application loads

Read/Write operations by **thousands/millions** of users

examples include

We should also remember Google's Bigtable and Amazon's SimpleDB. While these are tied to their host's cloud service, they certainly fit the general operating characteristics

IMPORTANT DESIGN GOALS

Scale out: designed for scale

- Commodity hardware
- Low latency updates
- Sustain high update/insert throughput

Elasticity – scale up and down with load

High availability – downtime implies lost revenue

- Replication (with multi-mastering)
- Geographic replication
- Automated failure recovery

LOWER PRIORITIES

No Complex querying functionality

- No support for SQL
- CRUD operations through database specific API

No support for joins

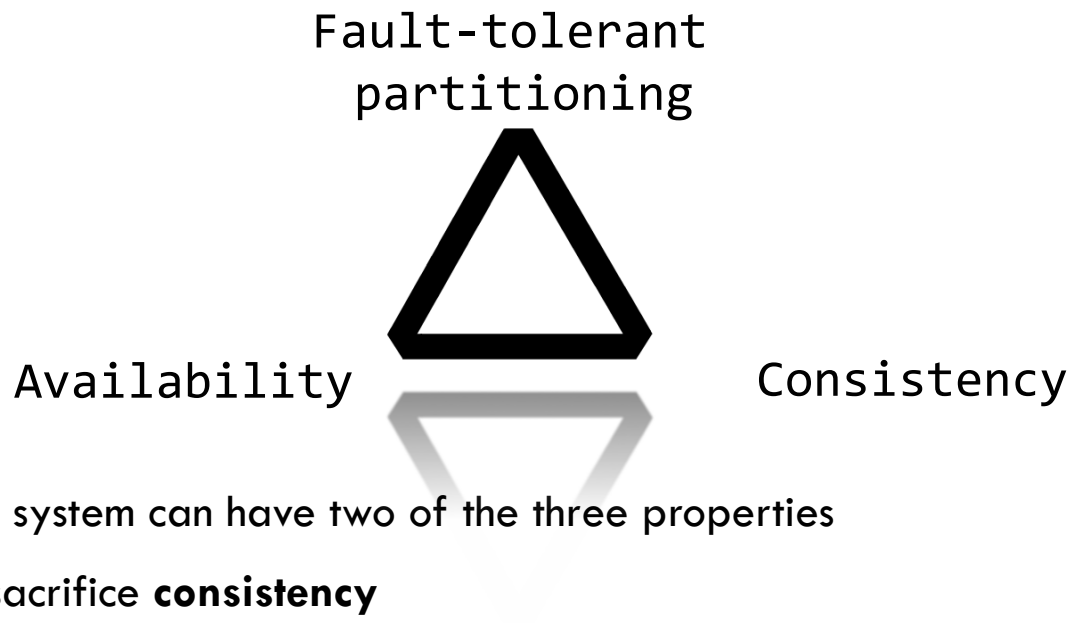
- Materialize simple join results in the relevant row
- Give up normalization of data?

No support for transactions

- Most data stores support single row transactions
- Tunable consistency and availability (e.g., Dynamo)

→ Achieve high scalability

NON FUNCTIONAL PROPERTIES



CAP theorem[1]: a system can have two of the three properties

NoSQL systems sacrifice **consistency**

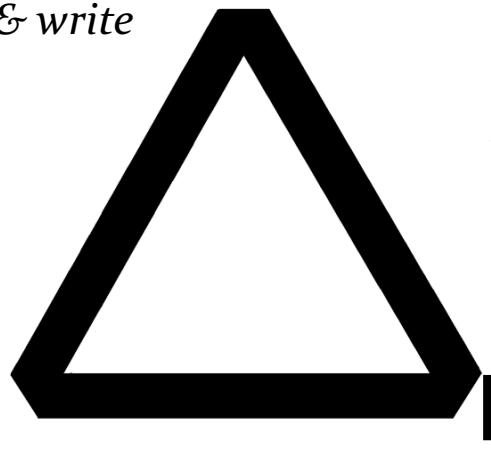
1 Eric Brewer, "Towards robust distributed systems." PODC. 2000 http://www.cs.berkeley.edu/~brewer/cs262b-2004/PODC-keynote.pdf

VISUAL GUIDE TO NOSQL SYSTEMS

Availability:
each client can always read & write

A

Data models
- Relational
- Key-Value
- Column oriented Tabular
- Document oriented



C - A
- RDBM's
- MySQL
- Postgres
- etc
- Aster Data
- GreenPlum
- Vertica

A - P
- Dynamo
- Voldemort
- Tokyo Cabinet
- KAI
- Cassandra
- SimpleDB
- CouchDB
- Riak

Consistency:
all clients always have the same view of de data

C

P

Partition tolerance:
The system works well despite physical network partitions

C - P
- BigTable
- HyperTable
- Hbase
- MongoDB
- TerraStore
- Scalaris
- BerkeleyDB
- MemcacheDB
- Redis

WHY SACRIFICE CONSISTENCY?

It is a simple solution

- nobody understands what sacrificing P means
- sacrificing A is unacceptable in the Web
- possible to push the problem to app developer

C not needed in many applications

- Banks do not implement ACID (classic example wrong)
- Airline reservation only transacts reads (Huh?)
- MySQL et al. ship by default in lower isolation level

Data is noisy and inconsistent anyway

- making it, say, 1% worse does not matter

CONSISTENCY MODEL

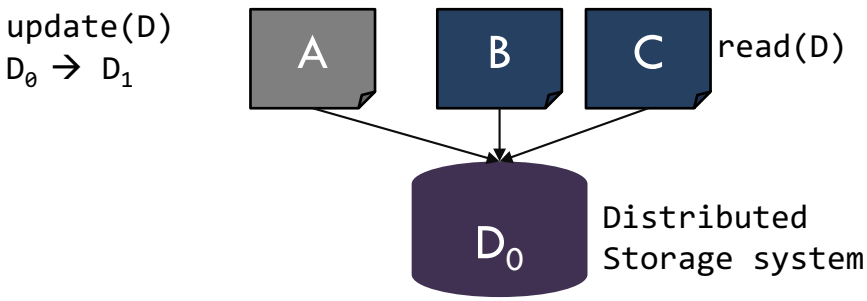
ACID semantics (transaction semantics in RDBMS)

- **Atomicity**: either the operation (e.g., write) is performed on all replicas or is not performed on any of them
- **Consistency**: after each operation all replicas reach the same state
- **Isolation**: no operation (e.g., read) can see the data from another operation (e.g., write) in an intermediate state
- **Durability**: once a write has been successful, that write will persist indefinitely

BASE semantics (modern Internet systems)

- **Basically Available**
- **Soft-state** (or scalable)
- **Eventually** consistent

CONSISTENCY MODELS



Strong consistency:

- After the update completes, every subsequent access from A, B, C will return D_1

Weak consistency:

- Does not guaranty that any subsequent accesses return D_1 -> a number of conditions need to be met before D_1 is returned

Eventual consistency: Special form of weak consistency

- Guaranty that if no new updates are made, eventually all accesses will return D_1

VARIATIONS OF EVENTUAL CONSISTENCY

Causal consistency:

- If A notifies B about the update, B will read D1 (but not C!)

Read your writes:

- A will always read D1 after its own update

Sessionconsistency:

- Read your writes inside a session

Monotonic reads:

- If a process has seen Dk, any subsequent access will never return any Di with i < k

Monotonic writes:

- Guaranty to seiralize the writes of the same process

ACID VS BASE

ACID

Strong consistency for transactions highest priority

Availability less important

Pessimistic

Rigorous analysis

Complex mechanisms

BASE

Availability and scaling highest priorities

Weak consistency

Optimistic

Best effort

Simple and fast

MAP-REDUCE

Programming model for expressing distributed computations on massive amounts of data

Execution framework for large-scale data processing on clusters of commodity servers

Market: any organization built around gathering, analyzing, monitoring, filtering, searching, or organizing content must tackle large-data problems

- data- intensive processing is beyond the capability of any individual machine and requires clusters
- large-data problems are fundamentally about ***organizing computations on dozens, hundreds, or even thousands of machines***

MAP REDUCE JOB

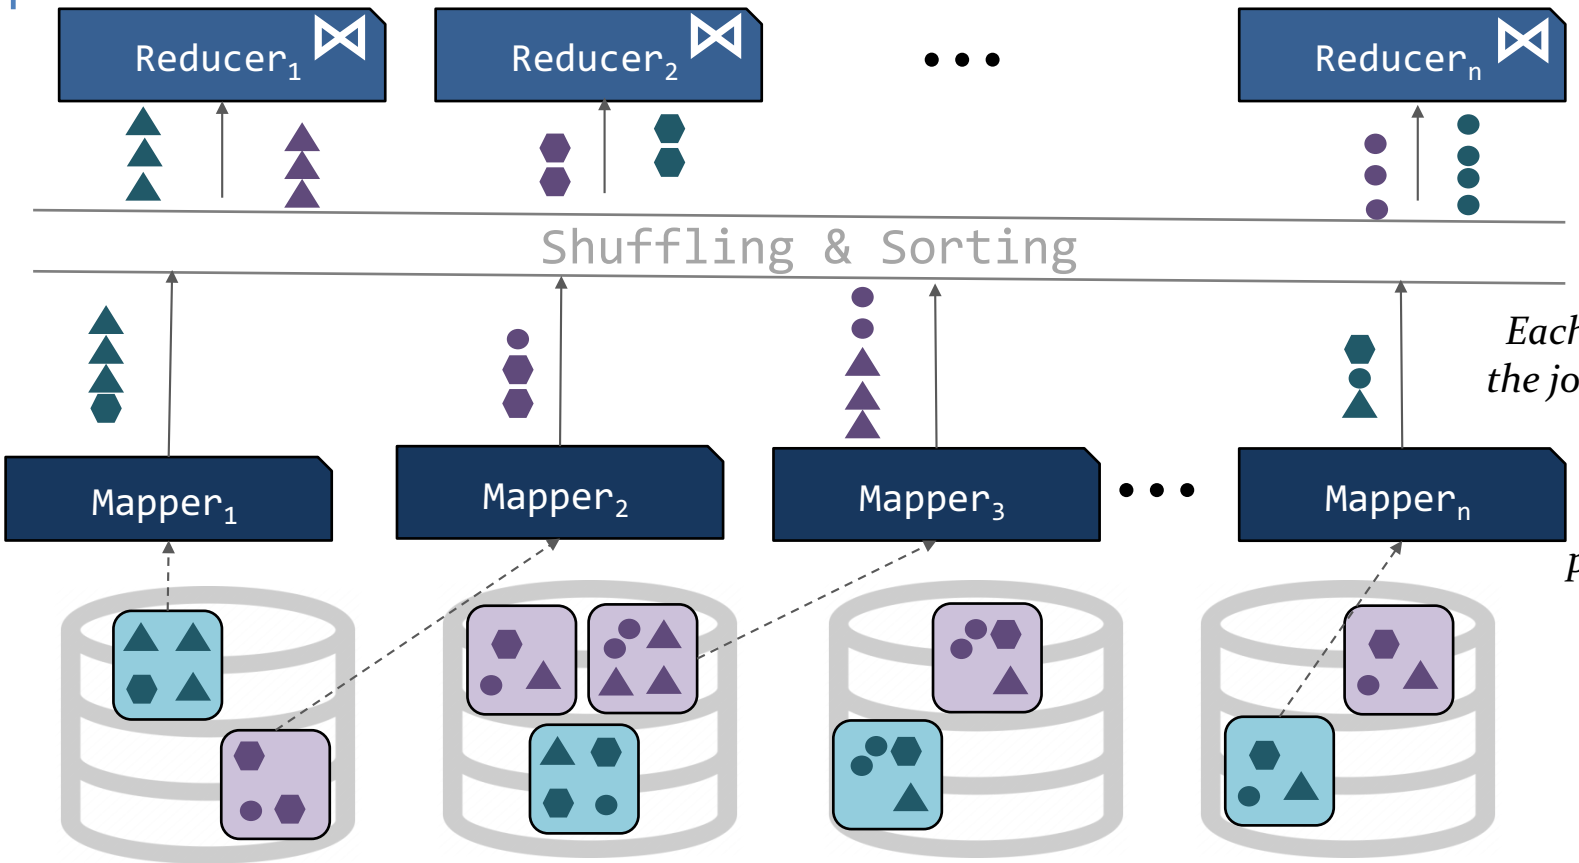
Stage 1: Apply a user-specified computation over all input records in a dataset.

- These operations occur in parallel and yield intermediate output (**key-value** pairs)

Stage 2: Aggregate intermediate output by another user-specified computation

- Recursively applies a function on every pair of the list

MAP REDUCE COMPLEX JOBS



Reducers perform the actual join

Each mapper produces the join key & the record pairs

Each mapper processes one block

HDFS stores data blocks

MAP REDUCE SUMMARY

Highly fault tolerant

Relatively easy to write "arbitrary" distributed computations over very large amounts of data

MR framework removes burden of dealing with failures from programmer

Schema embedded in application code

A lack of shared schema

Makes sharing data between applications difficult

Makes lots of DBMS "goodies" such as indices, integrity constraints, views, … impossible

No declarative query language

PIG

"Pig Latin: A Not-So-Foreign Language for Data Processing"

- Christopher Olston, Benjamin Reed, Utkarsh Srivastava, Ravi Kumar, Andrew Tomkins (Yahoo! Research)
- http://www.sigmod08.org/program_glance.shtml#sigmod_industrial_program
- http://infolab.stanford.edu/~usriv/papers/pig-latin.pdf

PIG

General description

High level data flow language for exploring very large datasets

Compiler that produces sequences of MapReduce programs

Structure is amenable to substantial parallelization

Operates on files in HDFS

Metadata not required, but used when available

Provides an engine for executing data flows in parallel on Hadoop

Key properties

Ease of programming

- Trivial to achieve parallel execution of simple and parallel data analysis tasks

Optimization opportunities

- Allows the user to focus on semantics rather than efficiency

Extensibility

- Users can create their own functions to do special-purpose processing

EXAMPLE

Top 5 pages accessed by users between 18 and 25 year

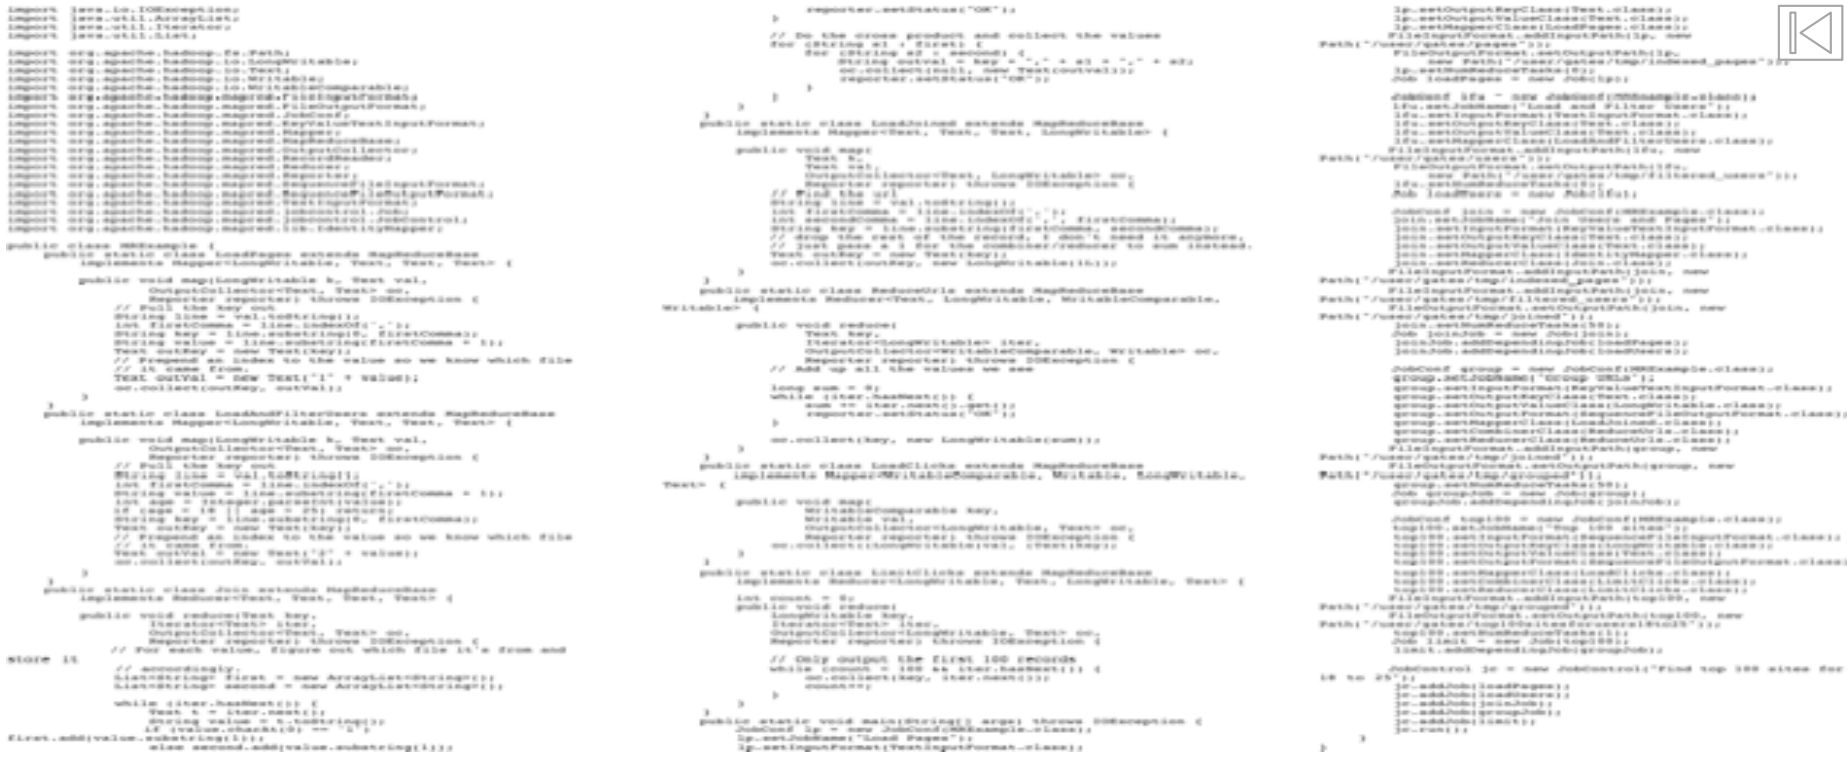
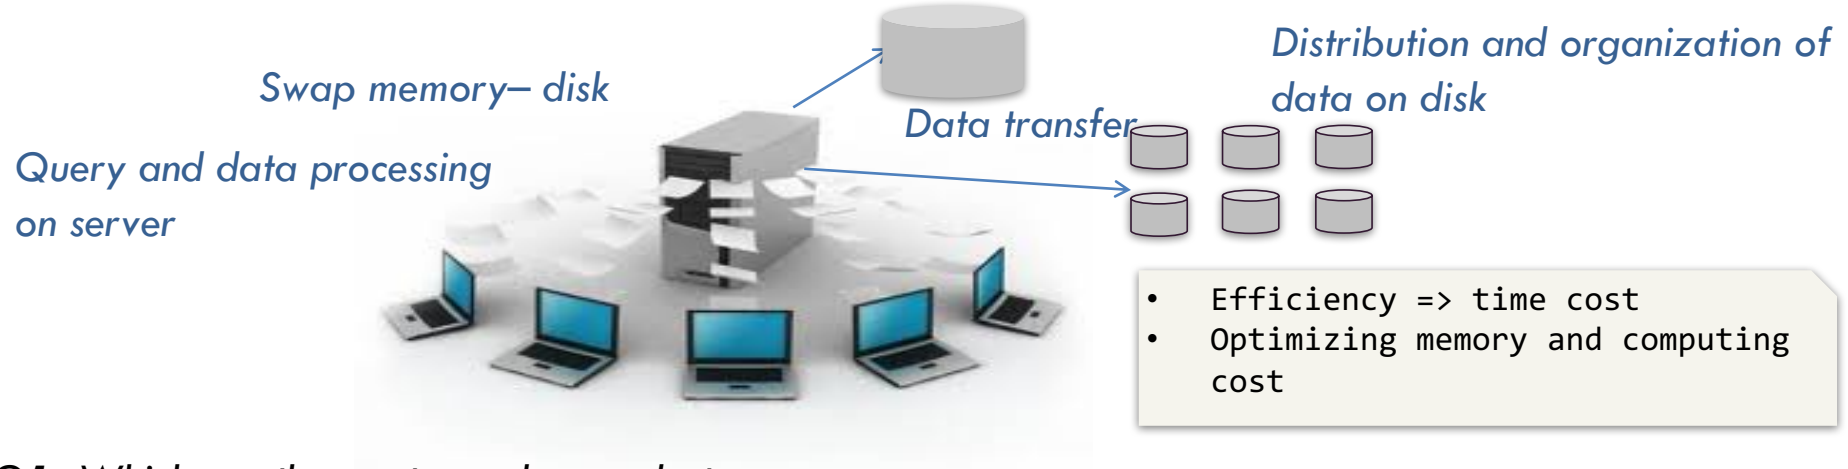
top_5 = limit sorted 5;
store top_5 into 'top_5_site

EQUIVALENT JAVA MAP REDUCE CODE



QUERYING **WITH** RESOURCES CONSTRAINTS



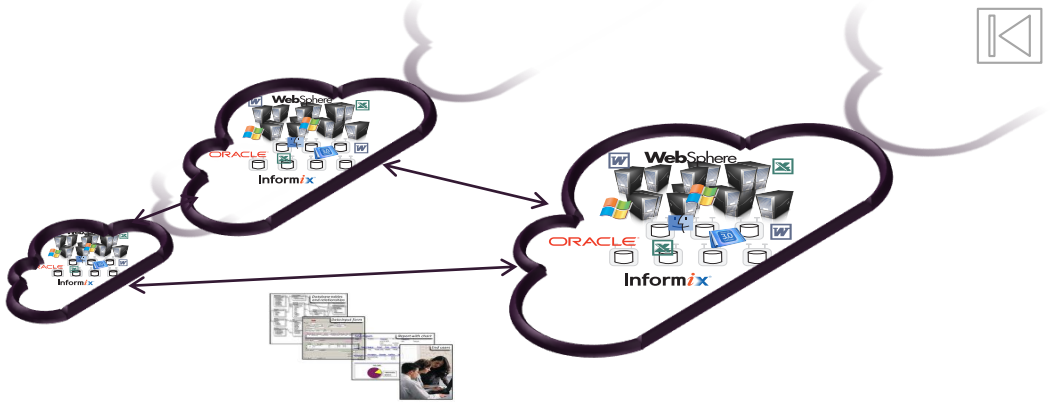
Q1: Which are the most popular products at Starbucks ?

Q2: Which are the consumption rules of Starbucks clients ?

Efficiently manage and exploit data sets according to given specific storage, memory and computation resources

QUERYING **WITHOUT** RESOURCES CONSTRAINTS

```
Costly => minimizing cost, energy
consumption
```



- Query evaluation→ How and under which limits ?
- Is not longer completely constraint by resources availability: computing, RAM, storage, network services
- Decision making process determined by resources consumption and consumer requirements

Data involved in the query, particularly in the result can have different costs: top 5 gratis and the rest available in return to a credit card number

Results storage and exploitation demands more resources

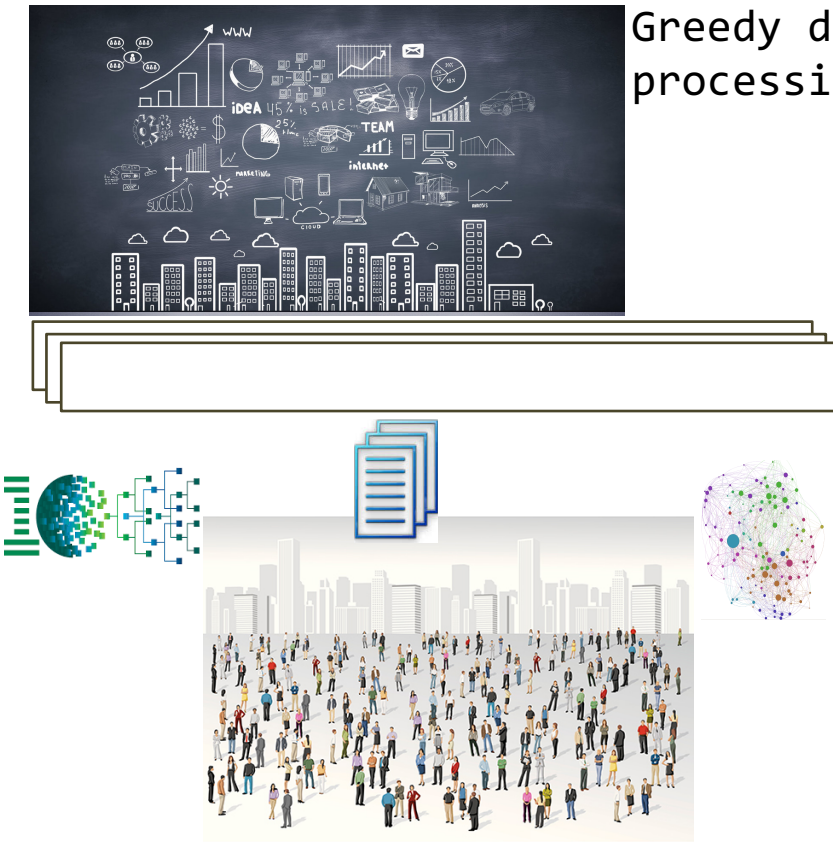
MULTIMODEL DATA MANAGEMENT

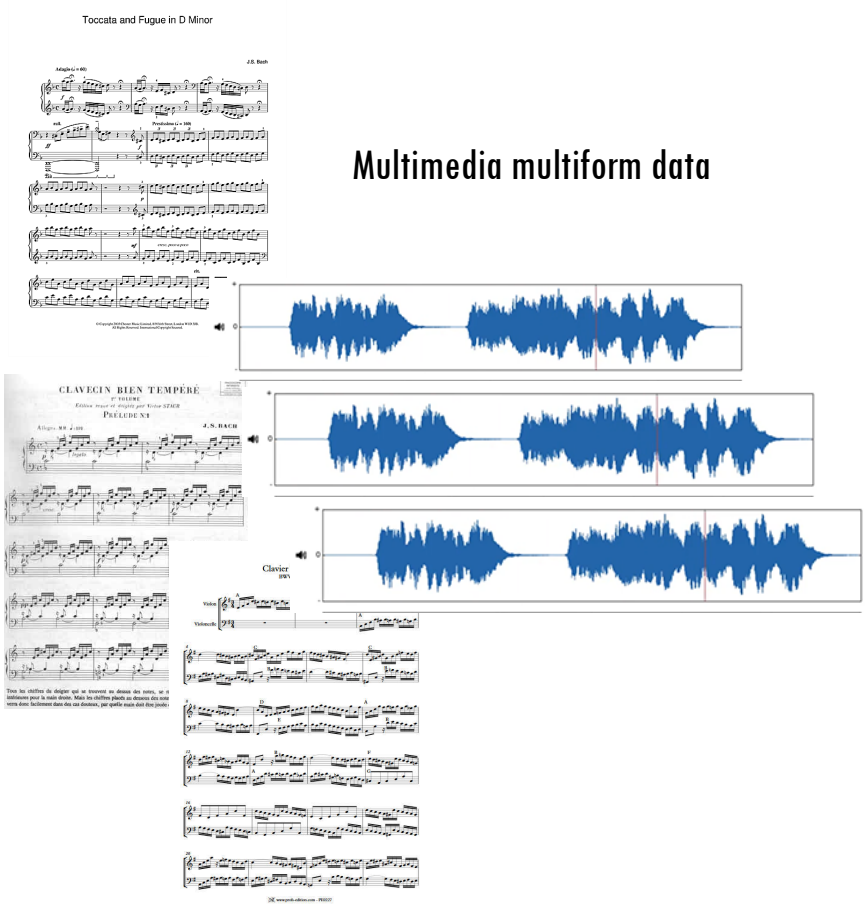


Greedy data processing

Provide data storage, fetching and delivery strategies

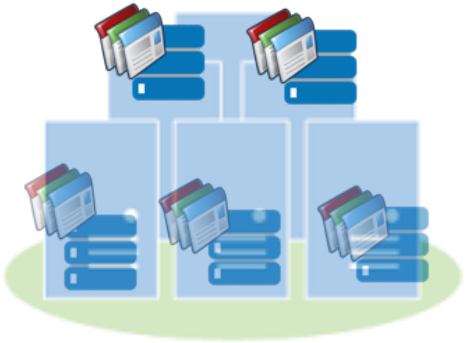
- Architecture: distributed file system across nodes
- Data sharding and replication: on storage and memory
- Fetch to fulfil multi-facetig application requirements
  - Prefetching
  - Memory indexing
  - Reduce impedance mismatch

DATA SHARDING



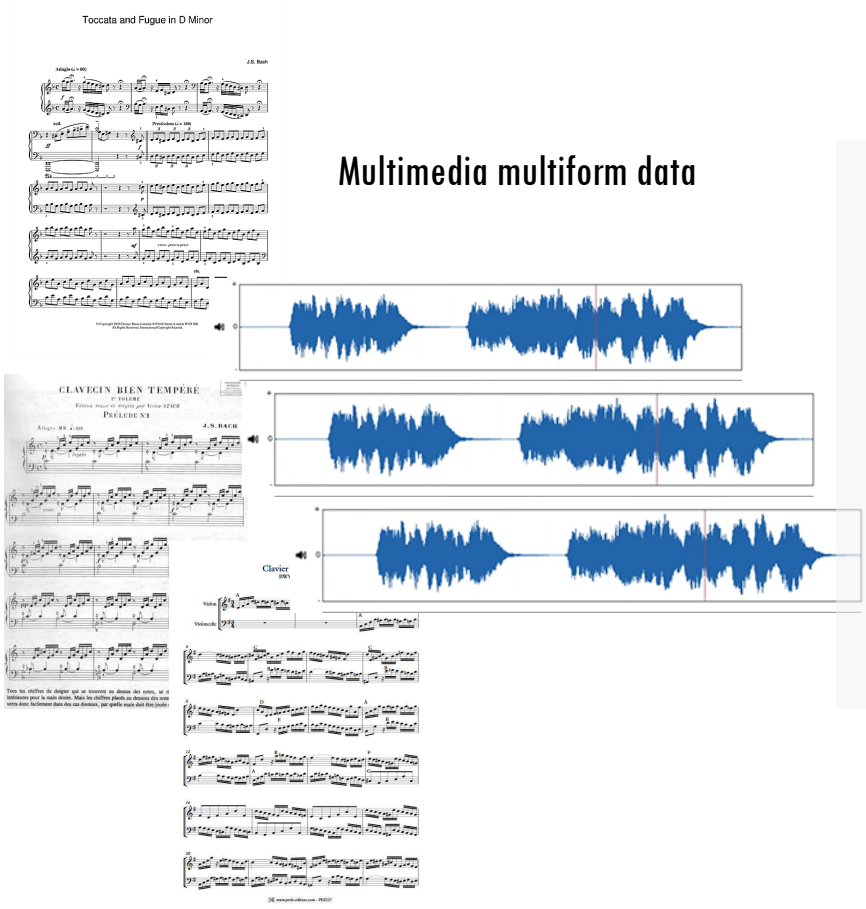
Multimedia multiform data

Distributed File System



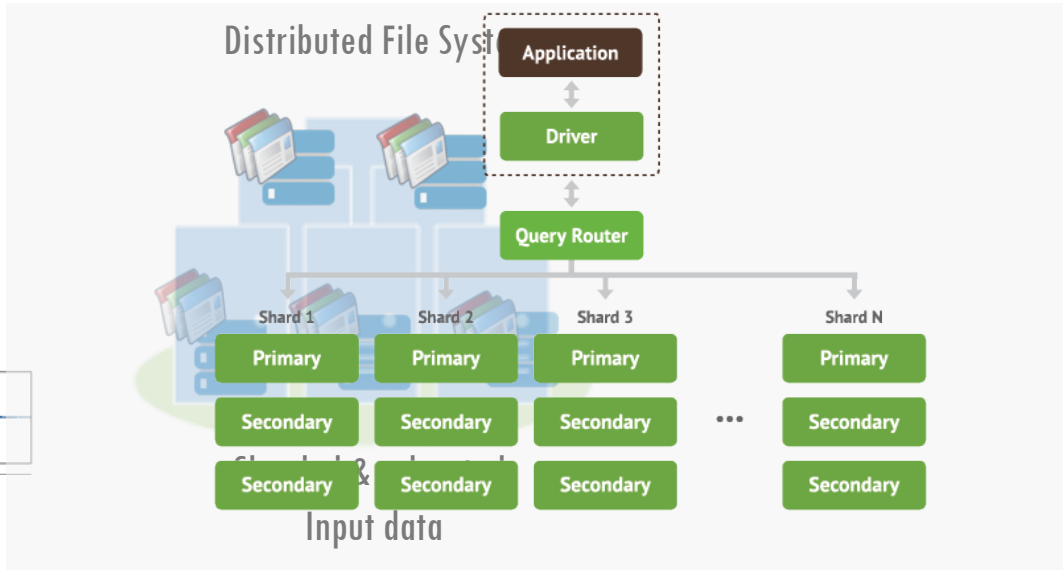
Sharded & colocated
Input data

DATA SHARDING



Multimedia multiform data

Sharded data architecture

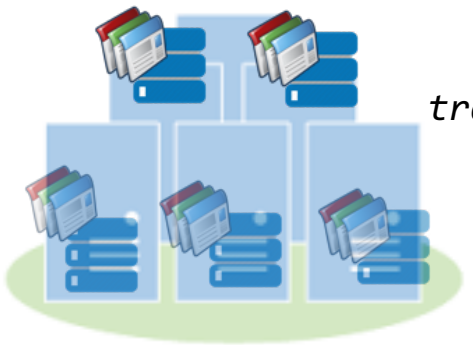


Factors:

- RAM
- CPU
- Disk
- Network

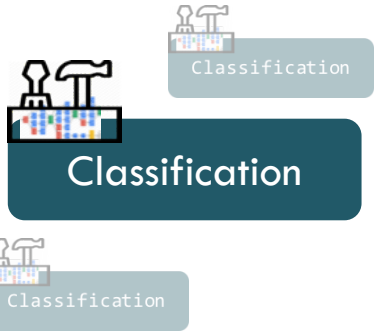
INDEXING & STORING

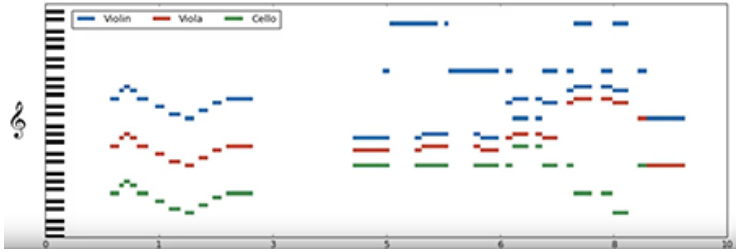
Distributed File System



Sharded & colocated
Input data

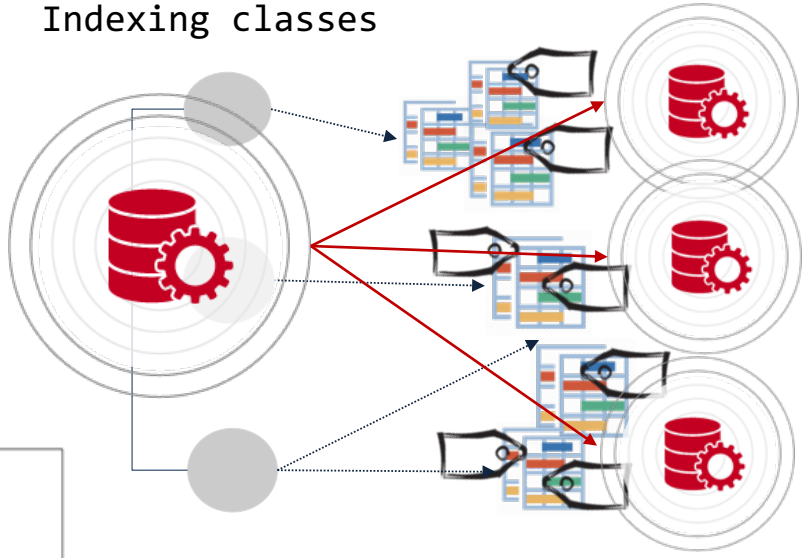
Data transformation





Multimedia
multiform data

Indexing classes

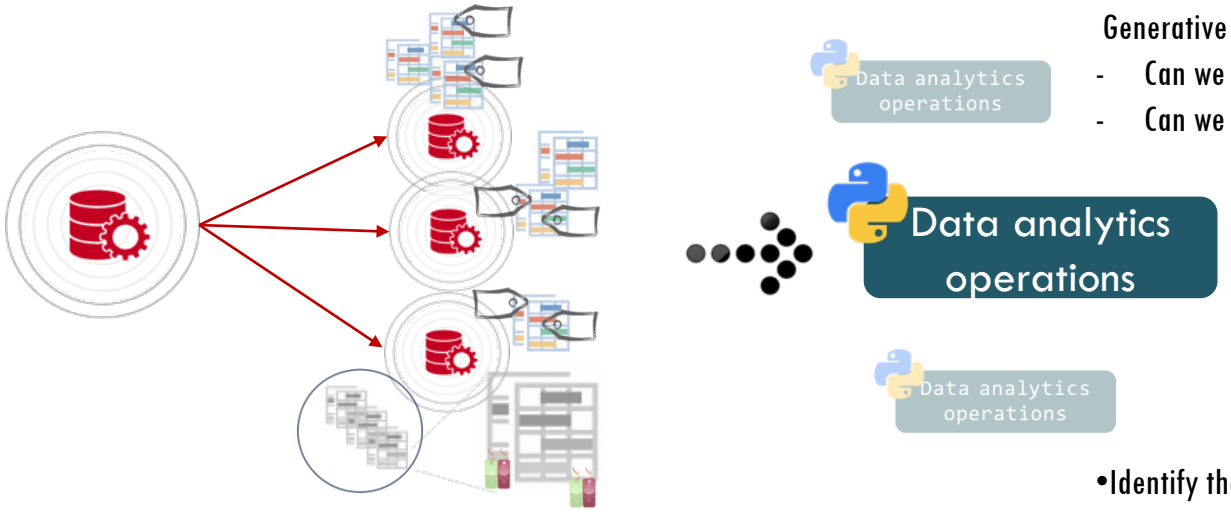


Tagged opus execution

- the precise time of each note every recording,
- the instrument that plays each note,
- the note's position in the metrical structure of the composition

MusicNet: 330 classical music recordings, 1 million annotated labels indicating http://homes.cs.washington.edu/~thickstn/musicnet.html

LOADING



Music information retrieval

- Automatic music transcription
- Inferring a musical score from a recording

Generative models that can fabricate performances under various constraints

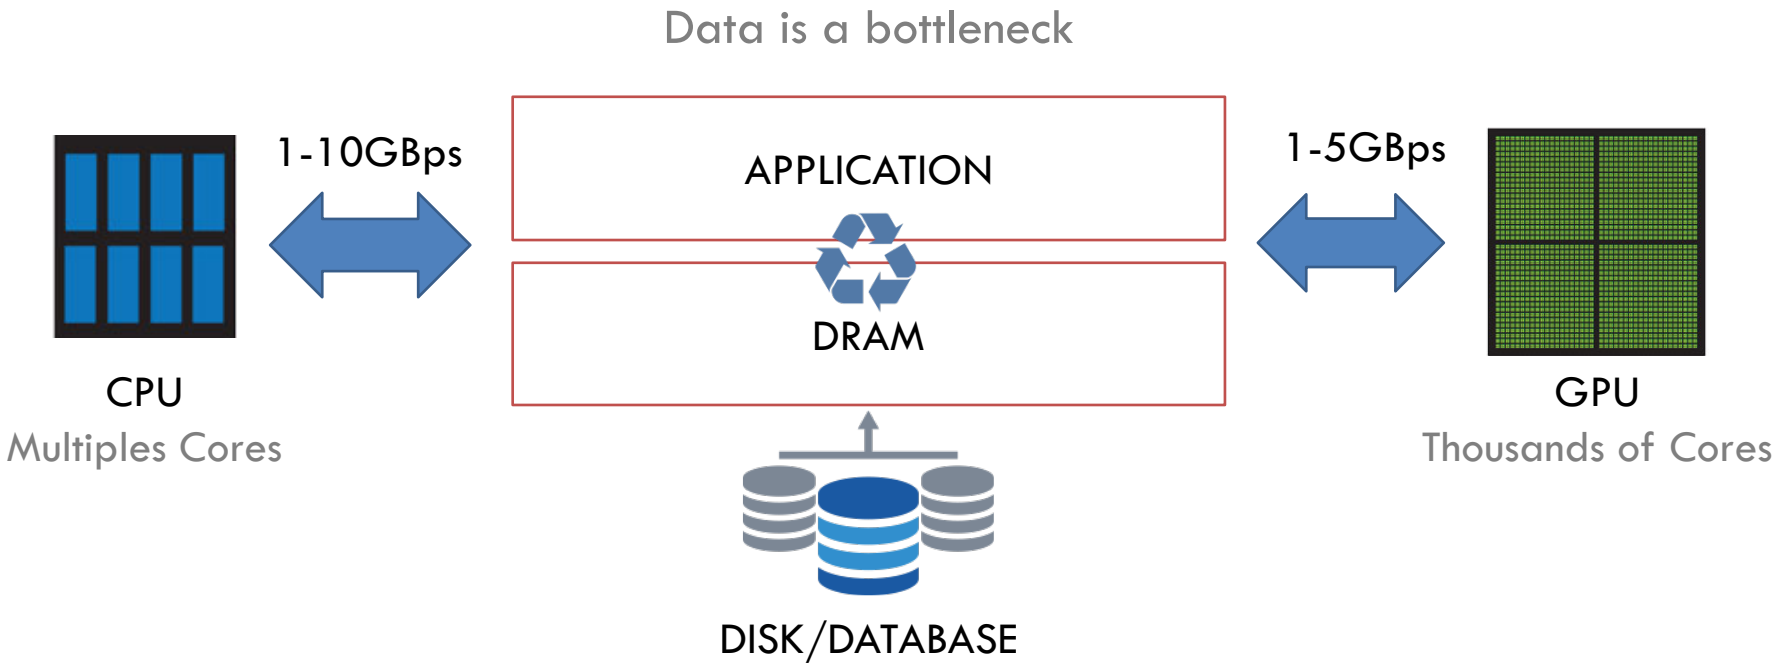
- Can we learn to synthesize a performance given a score?
- Can we generate a fugue in the style of Bach using a melody by Brahms?

- Identify the *notes* performed at specific times in a recording
- Classify the *instruments* that perform in a recording
- Classify the *composer* of a recording
- Identify precise *onset* times of the notes in a recording
- Predict the *next note* in a recording, conditioned on history

GREEDY DATA PROCESSING

"Multi-view computational problem"

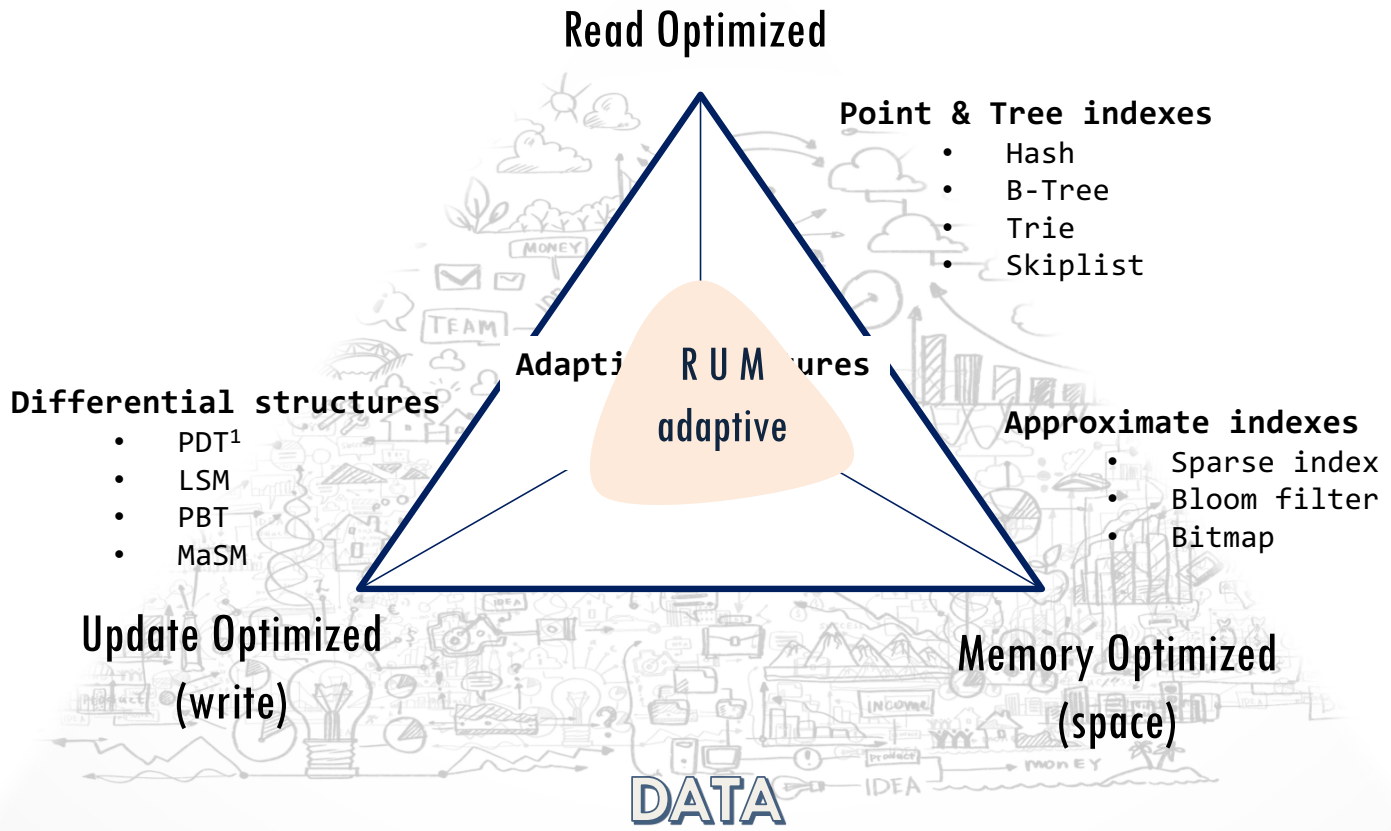
Iterative data processing and visualization tasks need to share CPU cycles



what can go wrong?

- not enough space to index all data
- not enough idle time to finish proper tuning
- by the time we finish tuning, the workload changes
- not enough money - energy - resources

ACCESS METHODS



Requirements

Operations

Hardware

Predefined Data Types, Log-structured Merge Tree, the Partitioned B-tree, the Materialized Sort-Merge algorithm

CHALLENGES & OBJECTIVE

How to combine, deploy, and deliver data management functionalities:

- **Compliant** to application/user requirements
- **Optimizing** the consumption of computing resources in the presence of **greedy** data processing tasks
- Delivered according to **Service Level Agreement (SLA)** contracts
- Deployed in **elastic** and distributed **platforms**
